1. About

1.1. Motivation

“In peridynamics, cracks are part of the solution, not part of the problem.”
— Florin Bobaru

1.2. Scope

This document is supposed to be the users guide for the creation of models, performing simulations with Peridigm and postprocessing with ParaView. It serves as an addition to the original user guide [1]. The open-source version of this document is based upon [2].

The document includes a growing quick reference guide to model options in Peridigm as well as conclusions to obtain proper results. Additionally, preferences and possibilities for the postprocessing of the simulation results with ParaView are part of the document.

For all things considering the installation of Peridigm and ParaView please consult the Peridigm Installation Guide which is part of the same repository as this document.

1.3. Contributors

This document represents a cumulative effort. The following list shows the contributors in alphabetic order by last name.

- Anna-Janina Bednarek
- Martin Rädel
- Lasse Wiedemann
- Christian Willberg
1.4. Peridynamic codes

Peridigm is one of several codes implementing peridynamics. Following are lists of known codes dealing with the numerical implementation of the peridynamic theory.

1.4.1. Production codes

Table 1.1.: Codes implementing peridynamics

<tr>
<td>(\overline{\mathbf{A}})</td>
<td>blackboard majuscule, underline</td>
<td>Double state</td>
</tr>
</tbody>
</table>

2.1.2. Coordinate systems

Peridigm uses a global cartesian right-hand coordinate system. Local coordinate systems are currently not available.

2.1.3. Unit systems

For the application of all methods, tools and solutions input values are required. It has to be made sure by the user to make sure that all input values are defined in a single
consistent unit system, like the SI- or imperial unit system. The following Table 2.2 shows some well-established unit systems.
### Table 2.2.: Consistent unit systems according to ANSYS /UNITS command

#### 2.1.4. Conversion between peridynamic and finite element values

**Material properties**

- **3D** Without plane stress or strain assumptions
- **2D** With plane stress or strain assumptions
Note, that in case of bond-based analysis, the conversion is problem-dependent:

\[
\nu = \begin{cases}
\frac{1}{3} & \text{3D & 2D plane strain} \\
\frac{1}{5} & \text{2D plane stress}
\end{cases}
\]  
(2.1)

### Table 2.3: Material property conversion

<table>
<thead>
<tr>
<th>Description</th>
<th>Dim.</th>

<td>[5]</td>
</tr>
</tbody>
</table>

Internally, Peridigm uses \( K \), \( G \) for the stiffness description. The conversion between engineering constants and \( K \), \( G \) is performed in methods

- `Peridigm::Material::calculateBulkModulus`
- `Peridigm::Material::calculateShearModulus`

in class `/src/Materials/Peridigm_Material.cpp`.

Currently, Peridigm only uses the 3D formulation of the peridynamics, e.g. for surface correction factors. Therefore, only the 3D equations shall be used for material modelling.

---

\[7\text{, p.120}\]
2.2. Model input file format

Peridigm requires two input files: the model and the mesh. This section describes the format of the model input file, while section 2.3 is devoted to the possible types of discretization and the respective formats.

2.2.1. Input deck structure

This section is basically taken from section 3.2 in [1]. Independent of the actual input file format, a Peridigm input deck takes the form:

- [Discretization Section] required
- [Materials Section] required
- [Damage Models Section] optional
- [Blocks Section] required
- [Contact Section] optional
- [Boundary Conditions Section] required
- [Compute Class Parameters Section] optional
- [Solver Section] required
- [Output Section] required

We elaborate on each of these sections below:

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Discretization Section]</td>
<td>Contains filename of input mesh, or arguments to Peridigm internal mesh generator.</td>
</tr>
<tr>
<td>[Materials Section]</td>
<td>Contains the names of the material models used and arguments for their constitutive parameters.</td>
</tr>
<tr>
<td>[Damage Models Section]</td>
<td>Contains the names of the damage models used and arguments for their constitutive parameters.</td>
</tr>
<tr>
<td>[Blocks Section]</td>
<td>Contains a listing of the model properties, associating each block with material and damage models as well as a horizon.</td>
</tr>
</tbody>
</table>

continued . . .
2. Peridigm - Basics

...continued

<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Contact Section]</td>
<td>Contains a listing of the contact models and the kind of contact model to be applied when model regions come into contact in a simulation.</td>
</tr>
<tr>
<td>[Boundary Conditions Section]</td>
<td>Contains the initial and boundary conditions and loads for the simulation.</td>
</tr>
<tr>
<td>[Compute Class Parameters Section]</td>
<td>Contains user defined calculation data which shall be output in a simulation.</td>
</tr>
<tr>
<td>[Solver Section]</td>
<td>Contains the solver to be used along with solver parameters.</td>
</tr>
<tr>
<td>[Output Section]</td>
<td>Contains the output filename and output frequency along with a listing of the variables to be output.</td>
</tr>
</tbody>
</table>

Each of these sections is described in a separate part of chapter 3.

2.2.2. Formats

Peridigm currently supports three different input file formats:

→ XML format
→ Free format
→ YAML format

Both, XML and free format are more or less obsolete and will not be part of future developments. For version 1.5 and beyond the focus is on the YAML format.

2.2.2.1. XML format

  <band height="20">
    <!--
    Hello,
    I am a multi-line XML comment
    <staticText>
      <reportElement x="180" y="0" width="200" height="20"/>
      <text><![CDATA[Hello World!]]></text>
    </staticText>
    -->
  </band>
</detail>
```

Format interference with the function parser

When you write a xml format document, you cannot use “>” or “<” directly. When you edit a xml document, you should use “&gt;” replace “>” and “&lt;” replace “<”, e.g.

```xml
<Parameter name="Value" type="string" value="if(t &lt;= 10.0e-6){value =45.8216*t;} else \{value=0;\}"/>
```

instead of

```xml
<Parameter name="Value" type="string" value="if(t <= 10.0e-6){value =45.8216*t;} else \{ value=0;\}"/>
```

2.2.2.2. Free format

Comment sign

A comment line is started with the hash sign: #.
2.2.2.3. YAML format

Comment sign

A comment line is started with the hash sign: #. Comments can start anywhere on a line, and continue until the end of the line. YAML does not support block comments.

2.2.3. Input file parser

The input is parsed directly in the Peridigm.cpp class in src/core/.

The input of keywords seems to be case-insensitive.

2.2.4. Function parser

2.2.4.1. Preliminaries

Description

You can use functions inside a Peridigm input deck. This means, it is possible to use algebraic expressions, e.g. for the definition of boundary conditions. Peridigm uses the RTCompiler function parser to process C-style expressions for the specification of input parameters, including initial and boundary conditions. The RTCompiler (RTC) is used via the Trilinos PG_RuntimeCompiler class.

History

The internal mechanism for processing functions used to be muParser, and was recently changed to rtcompiler, see this commit.

2.2.4.2. Supported operations

The RTC language can be thought of as a small subset of the C language with a couple minor modifications. The following information is repeated from the RTCompiler source code documentation.
Operators

The RTC language has the following operators that work exactly as they do in C and have the same precedence as they do in C:

- Addition
- Subtraction
- Negation
- Multiplication
- Division
- Exponentiation
- Equality
- Greater than
- Less than
- Greater than or equal to
- Less than or equal to
- Assignment
- Logical or
- Logical and
- Inequality
- Modulo
- Logical not

Control flow

The RTC language has the following control flow statements:

- for( expr ; expr ; expr ) { ... }
- while( expr ) { ... }
- if (expr) {...}
- else if (expr) {...}
- else {...}

These control flow statements work exactly as they do in C except that the code blocks following a control flow statement **MUST** be enclosed within braces even if the block only consists of one line.

Line Structure

The line structure in the RTC language is the same as that of C. Expressions end with a semicolon unless they are inside a control flow statement.

According to this commit the .peridigm input deck format (free format) does not support multi-line entries.

---

This operator does not occur in the C language, but is added into the RTC language for convenience.
Math

The following `math.h` functions are available in RTC. Peridigm also seems to support the APREPRO functionalities. The features are reported in [10].

2.2.4.3. Variables

User variables

Definition

It is possible to define your own variables for use inside a Peridigm input deck. The variables have to be defined at the beginning of the input deck. For YAML-input this is before the line `Peridigm:`. The definition starts with a hash key, followed by the variable name, the equal sign and subsequently the variable value. It is possible to perform algebraic operations inside the variable definition.

```yaml
#{LENGTH=1.0}
#{WIDTH=0.25}
#{NUM_ELEM_ALONG_WIDTH=5}
#{ELEMENT_SIZE=WIDTH/NUM_ELEM_ALONG_WIDTH}
#{HORIZON=0.15}
```

Usage

A variable value is used inside the model definition by calling the variable name in curly braces, e.g. for the variable `HORIZON` is the following example excerpt of a block definition in an input file:

```
Blocks:
    Block_1:
        Block Names: "Block_1"
        Material: "testmaterial"
        Horizon: {HORIZON}
```

Pre-defined variables

There are several pre-defined variables that can be used in the input deck. They are defined in `/src/core/Peridigm_BoundaryCondition.cpp`

The current list contains:
Variable | Description
--- | ---
t | Time
x | x-position of a peridynamic collocation point in the global cartesian coordinate system at time t
y | y-position of a peridynamic collocation point in the global cartesian coordinate system at time t
z | z-position of a peridynamic collocation point in the global cartesian coordinate system at time t
value | Prefix for string keyword entries

2.2.4.4. List of examples

> /examples/twist_and_pull/twist_and_pull.peridigm
2.3. Discretization input file format

2.3.1. Preliminaries

The mesh-free discretization for Peridigm consists of peridynamic collocation points with coordinates in three-dimensional space and an associated volume.

The discretization can either be an Albany multiphysics or Exodus finite element mesh or the peridynamic collocation points can be input directly. In case of the Albany or Exodus mesh description, the conversion from the finite element mesh to the peridynamic collocation points is performed internally by Peridigm for a number of supported element types. The supported element types are explained in the respective sections.

The discretization is generally stored in an external file and input into the Peridigm model file by referencing the discretization file name.
2.3.2. Text File – Direct collocation point text file input

2.3.2.1. Description

Discretization based on the direct specification of peridynamic collocation points.

2.3.2.2. Mesh file layout

The ASCII mesh file is space-separated. It consists of the following five columns in this order:

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
<td>x-coordinate of the peridynamic collocation point in the global cartesian coordinate system</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
<td>y-coordinate of the peridynamic collocation point in the global cartesian coordinate system</td>
</tr>
<tr>
<td>3</td>
<td>z</td>
<td>z-coordinate of the peridynamic collocation point in the global cartesian coordinate system</td>
</tr>
<tr>
<td>4</td>
<td>block_id</td>
<td>Block-ID for property assignment</td>
</tr>
<tr>
<td>5</td>
<td>volume</td>
<td>Collocation point volume</td>
</tr>
</tbody>
</table>

Following is an exemplary input file where all points belong to Block 1 and have the same volume 1.0.

```
# x  y  z  block_id  volume
-1.0  -0.5  0.5  1  1.0
-1.0  -0.5  -0.5  1  1.0
-1.0   0.5  0.5  1  1.0
-1.0   0.5  -0.5  1  1.0
...
```

2.3.2.3. Code

```python
from src/io/discretization/
    - Peridigm_TextFileDiscretization.cpp
    - Peridigm_TextFileDiscretization.hpp
```
2.3.3. Exodus – finite element mesh

2.3.3.1. Description

Discretization based on a finite element mesh in binary Exodus format.

2.3.3.2. Mesh file layout

To get an idea how the binary exodus format is setup have a look at [11].

Convert binary Exodus mesh to ASCII text file

The Exodus format uses the HDF5-library and especially the included NetCDF-C library. NetCDF-C provides tools to convert the binary Exodus format to a human-readable ASCII equivalent and vice-versa. NetCDF-C is required to build Peridigm. Therefore, if Peridigm is available on your system, these tools are also available. In case Peridigm is not installed on your system, use the FETranslator User Guide from the FESuite-Repository for instructions on how to install the necessary tools on your operating system.

In case you want to convert the binary mesh in file $FILE.g$ into a normal text file, open a command line and type

```
ncdump $FILE.g > $FILE.g.ascii
```

Afterwards, the file $FILE.g.ascii$ contains the text file.

Convert a ASCII text file into a binary Exodus mesh

In case you prepared an ASCII text file $FILE.g.ascii$ which is the equivalent of a binary Exodus mesh file, you can translate the text file to a binary mesh file $FILE.g$ with

```
ncgen -o $FILE.g $FILE.g.ascii
```

2.3.3.3. Code

```
/sr/io/discretization/Peridigm_ExodusDiscretization.cpp
/sr/io/discretization/Peridigm_ExodusDiscretization.hpp
```

DLR – DLR-IB-FA-BS-2018-23
2.3.3.4. Possibilities to create format

Finite element meshes in the *Exodus* format can be created using

- CUBIT  
- gmsh → vtk → exodus  
- gmsh-exodus-converter

2.3.3.5. Supported element types

**SPHERE_ELEMENT**

From Sierra/SolidMechanics

**TET_ELEMENT**

Sketch: TO-DO

10-node tetrahedron elements are treated as 4-node tetrahedron elements. Middle nodes on the element edges are discarded.

Method for conversion: `tetCentroidAndVolume` in `Peridigm_GeometryUtils.cpp`

**HEX_ELEMENT**

Sketch: TO-DO

20-node hexahedron elements are treated as 8-node hexahedron elements. Middle nodes on the element edges are discarded.

Method for conversion: `hexCentroidAndVolume` in `Peridigm_GeometryUtils.cpp`
2.3.3.6. How the conversion between FE mesh to Peridigm collocation points works

Von: Littlewood, David John [mailto:djlittl@sandia.gov]
Gesendet: Donnerstag, 10. März 2016 17:46
An: Parks, Michael L; Rädéel, Martin
Cc: peridigm-users@software.sandia.gov
Betreff: Mesh conversion

Martin,

As Mike said, Peridigm uses the approach of converting a hex or tet element into a single nodal volume. The routines in Peridigm are called tetCentroidAndVolume() and hexCentroidAndVolume(), which are in Peridigm_GeometryUtils.*pp. The routine for converting a 4-noded tet is trivial. The conversion routine for a 8-noded hex operates by dividing the hex into 24 tets, using temporary points at the face barycenters and one at the element barycenter. Once we have the 24 tets, the conversion routines for tets are applied and the results appropriately summed together to get the hex centroid and volume. The tet routines are exact, and the hex routines are exact if the hex has planar faces. If the hex has non-planar faces, the routines result in a faceted approximation of the hex. The use of 24 hexes guarantees that the approach is not orientation dependent. It would be possible, I believe, to do something more complex using finite-element shape functions, but this involves making some assumptions (the code is given only node and connectivity information, information on shape functions is generally not included in mesh files).

For 10-noded tets and 20-noded hexes, Peridigm ignores all the “extra” nodes and considers only the 4 corner nodes for a tet and the 8 corner nodes for a hex.

One thing to be aware of is the need to transfer node sets from the original hex/tet mesh to the peridynamic discretization. The Peridigm algorithm includes the newly-created nodal volume in a node set if any of the nodes in the original element are in the node set. Peridigm ignores sides sets, as they are generally used for applying pressure/traction loads, which are not directly applicable to nonlocal models and/or meshfree discretizations.

The result of the conversion routine is a point cloud that defines (x, y, z, volume, block_id) for each node in the discretization. In the code, the block_id is used to associate a material model with the nodal volume, as well as some other operations.

One caution regarding converting pre-existing hex/tet meshes is that peridynamics is not well suited to handle highly graded meshes. The mesh does not need to be uniform, but if the mesh contains elements with, for example, 10-to-1 differences in element size, you’ll run into problems. In this case, you’ll have to choose a horizon that is several times larger than the large elements, leading to the situation where the horizon is many times larger than the smallest elements. In most cases this fails to achieve the high fidelity you
were looking for in the highly-refined portion of the mesh, and it can really hurt code performance.

Your options for reading in pre-existing mesh are 1) convert the mesh to exodus/genesis format, in which case Peridigm can read it directly and takes care of everything, 2) pre-process the mesh yourself and create a text file with (x, y, z, volume, block_id) information and use Peridigm’s text-file reader, or 3) implement a new discretization type that reads your mesh files into Peridigm. In the last case, you’d be able to leverage a lot of the code in the existing exodus file reader, but obviously the specifics of the file format would be different.

If it were me, I’d go with option 1), and I’d use the exodus.py python tool that is distributed as part of SEACAS. The SEACAS package is distributed with Trilinos, so you should have access to that already if you’re running Peridigm. There’s a learning curve associated with the exodus format, but if you’re able to convert to exodus format then you can use all the SEACAS utilities, for example decomp for creating parallel decompositions. (Side note, technically exodus is an output file format, and genesis is the corresponding input file format, but in practice people call both of them exodus.)

Hope this helps, Dave

3.2. Discretization tools

3.2.1. Preliminaries

Tools to modify the discretization behavior.

3.2.2. Bond Filters

3.2.2.1. Description

A method to omit bonds in the discretization.

3.2.2.2. Code

Dependent on the type of discretization the following classes are used:

> from src/io/discretization/:

- Peridigm_AlbanyDiscretization.cpp
- Peridigm_AlbanyDiscretization.hpp
- Peridigm_ExodusDiscretization.cpp
- Peridigm_ExodusDiscretization.hpp
- Peridigm_PdQuickGridDiscretization.hpp
- Peridigm_PdQuickGridDiscretization.cpp
- Peridigm_TextFileDiscretization.hpp
- Peridigm_TextFileDiscretization.cpp

All extend the super-class

> /src/io/discretization/Peridigm_Discretization.cpp
> /src/io/discretization/Peridigm_Discretization.hpp

Each class uses the method from the super-class:

PeridigmNS::Discretization::createBondFilters
3. Peridigm - Quick reference guide

</tr>
<tr>
<td>Side_Length</td>
<td>double</td>
<td>✓</td>
<td>-</td>
<td>Length of rectangle left and right edges</td>
</tr>
</tbody>
</table>

Remarks

1. Bond Filters cause the bonds to not be created in the first place
2. For type “Rectangular_Plane”:
   - Define a rectangular cut plane where all bonds are released prior to the simulation.
3. It is suggested to define the output variable Number_Of_Neighbors in order to confirm that the bond filter is in the right place. It always seems to take me multiple tries to get it right.
Usage

The input parameters form a 2D rectangle in 3D space. Bonds that would pass through the rectangle are not formed, which creates a pre-crack.

![Diagram of Bond Filter - Rectangular Plane](image)

Figure 3.1: **Bond Filter - Rectangular Plane**

- **Lower_Left_Corner**: Point in 3D which defines the origin of the rectangle in its lower left corner, here named “1”.
- **Bottom_Unit_Vector**: Vector of unit length in 3D defining the direction along the bottom of the rectangle, here from “1” to “2”.
- **Normal**: Vector in 3D that defines the normal direction of the rectangle. From this and **Bottom_Unit_Vector** the vector of the other side of the rectangle, here from “1” to “4”, is calculated internally using the vector or cross product.
- **Bottom_Length**: Length of the side along **Bottom_Unit_Vector**, so the length between “1” to “2” and “3” to “4”.
- **Side_Length**: Length of the others two sides, here “1” to “4” and “2” to “3”.

3.2.2.5. List of examples

- From test/regression/:
  - PrecrackedPlate/PrecrackedPlate.xml
  - PrecrackedPlateTwoCracks/PrecrackedPlateTwoCracks.xml
3.2.3. Influence Function

3.2.3.1. Description

The influence function in the peridynamic theory is used to weight the contribution of all the bonds participating in the computation of volume-dependent properties dependent of the distance to the family origin.

3.2.3.2. Literature

[12]  
[13]

3.2.3.3. Code

Release version

Available from version 1.2.

Required compiler options

-

Routines

[ src/core/:

- Peridigm_Peridigm_InfluenceFunction.cpp
- Peridigm_Peridigm_InfluenceFunction.hpp

3.2.3.4. Input parameters

List

The influence function is not an individual object. Therefore, no parameter list is required here.
Remarks

1. The influence function is defined for the whole model.
2. Function values are dependent of the bond length $|\xi|$ and the local horizon $\delta$.
3. The influence functions in Figure 3.2 are pre-implemented. Each unrecognized string is assumed to be an user-defined influence function. The default value is set to One in case the keyword is not specified, see Peridigm.cpp.

![Figure 3.2: Influence functions](image)

(a) One  (b) Parabolic Decay  (c) Gaussian

4. For further information on the effect of the influence function see: [12] & [15].
5. Other Influence functions and their usage can be found in [14]. The “Parabolic Decay” is used in [16]. Several different functions can be found in the literature for the “Gaussian” influence function:

→ [13, 17]:

$$\omega_{\xi}(\xi) = e^{-\left(\frac{|\xi|}{\beta}\right)^2}$$

→ [14]:

$$\omega_{\xi}(\xi) = e^{-\left(\frac{|\xi|}{\beta\alpha}\right)^2}$$

Here, the version from [14] is used\(^1\).

3.2.3.6. List of examples
3.3. Material models

3.3.1. Preliminaries

Generally, material models or more generally peridynamic constitutive laws are divided by
the underlying peridynamic formulation and can be grouped into two categories:

- **Bond-based** bond forces depend only on a single pair of material points
- **State-based** bond forces depend on deformations of all neighboring material points

A rough classification of material models in Peridigm can be found in Figure 3.3.

![Classification of peridynamic material models](image)

Bond-based material models are not discussed here any further. Peridynamic state-based
material models are further divided in two main classes, the

- **non-correspondence** and
- **correspondence**

materials. The non-correspondence is material created directly in the peridynamic for-
mulation. The correspondence material is formulated in the classical continuum mechanical
way. Both material classes will/should evaluate the same result for the same material modeled if surface effects have no influence. However, the correspondence material gives additional outputs as Cauchy stresses. This makes the results more comparable to the standard formulation.

### 3.3.1.1. Comments on non-correspondence material models

**Description**

There are sub-classes of non-correspondence material models. The first material model implementation is the peridynamic micro-brittle (PMB) material for bond-based peridynamics. Due to the limitations of bond-based peridynamics, this is not further discussed here.

State-based non-correspondence material models are the linear peridynamic solid (LPS) model and its extension to other types of material behaviour, like plasticity or viscoelasticity. These materials suffer from one large disadvantage, the underlying mathematical models assume that all points within are in the bulk. However, points near the surface are missing bonds. Missing bonds imply and induce incorrect material properties. Thus, these models are consistent.

To overcome this limitation, the so-called Position-Aware class of material models was developed.

**Remarks**

- If not stated otherwise, peridynamic solid non-correspondence (PS) materials in Peridigm do not have surface correction implemented.
- Position-aware (PA) materials were developed to account for missing bonds on surfaces removing the need for auxiliary surface correction techniques.

### 3.3.1.2. Comments on correspondence material models

- Do not require surface correction
- Might suffer from zero-energy modes
- Each family needs at least 3 non-collinear bonds active, otherwise the deformation gradient can not be calculated and the solution fails.
- Therefore, the bond check algorithm included in the interface aware damage model (cf. section 3.4.4) has to be included if a damage model should be used.
3.3.2. Elastic

3.3.2.1. Description

An isotropic, linear elastic material model. This material is also commonly known as the linear peridynamic solid (LPS) material model. The model does not support a flexible horizon, therefore a constant horizon for each block is assumed.

3.3.2.2. Literature

→ [18]

3.3.2.3. Stiffness model sketch

![Stiffness model sketch](image)

<td>-</td>
<td>false</td>
<td>Plane strain formulation</td>
</tr>
<tr>
<td>Plane Stress(^d)</td>
<td>bool</td>
<td>-</td>
<td>false</td>
<td>Plane stress formulation</td>
</tr>
</tbody>
</table>
Remarks

1. The stiffness can be defined by either elastic modulus combination: Volumetric and shear elasticity \((K,G)\) or the engineering constants \((E,\nu,G)\).
2. In case engineering constants are used, only two of the three values Young’s Modulus, Poisson’s Ratio and Shear Modulus have to be specified. The missing value is calculated from

\[
G = \frac{E}{2 \cdot (1 + \nu)}
\]

Internally, the engineering constants are converted to \((K,G)\).
3. Consider the general remarks on non-correspondence materials in section 3.3.1.1.
4. Activate plane strain or plane stress formulation for 2D analyses, cf. Equation (8) in [19]. Both or mutually exclusive. If none of the two parameters is used, the default 3D formulation is applied.

3.3.2.6. Exemplary input section

XML-format

Using engineering constants:

```xml

3.3.16. Vector Poisson
3.3.17. Multiphysics Elastic
3.4. Damage Models

3.4.1. Preliminaries

The damage models determine whether a bond is damaged or not. Failure of a bond is irreversible. Currently, degradation or material softening of a bond is not implemented. However, successive failure of individual bonds leads to an degradation for the integral material response.
3.4.2. Critical Stretch

3.4.2.1. Description

The critical stretch criterion compares the tensile stretch of a local bond with a critical value. After reaching the critical stretch there is no softening or stiffness degradation (0-th order). This criterion only uses tensile force components.

The critical bond stretch $s_C$ for a microbrittle material is related to energy release rate $G_{OC}$ and the discretization by means of the horizon.

The definition of the critical stretch is dependent on the model dimension and the peridynamic formulation. Since, currently, solely 3D-models are implemented in Peridigm only the respective equations are given here. For the equations of other model dimensions check the Peridigm Models and Verification Guide. Different equations exist for the state-based peridynamics and the special case of the bond-based peridynamics.

Beware, the following equations are based on the Griffith theory which assumes a pre-existing crack. If and how these relationships are valid for crack initiation must be investigated separately.

**Bond-based material models**

The definition of the critical stretch from Table 2.3:

$$s_C = \sqrt{\frac{10G_{OC}}{\pi c \delta^5}} = \sqrt{\frac{5G_{OC}}{9K \delta}}$$  \hspace{1cm} (3.1)

With the bulk modulus $K$, the horizon $\delta$ and the micromodulus or bond constant $c$ from Table 2.3.

**State-based material models**

The definition of the critical stretch from Table 2.3:

$$s_C = \sqrt{\frac{G_{OC}}{3G + \left(\frac{3}{4}\right)^4 \left(K - \frac{5G}{3}\right) \delta}}$$  \hspace{1cm} (3.2)

<td>✓</td>
<td>-</td>
<td>Critical bond stretch</td>
</tr>
<tr>
<td>Thermal Expansion Coefficient(^2,3)</td>
<td>double</td>
<td>-</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

Remarks

1. The critical bond stretch is dependent of the horizon \(\delta\). Therefore, it is no pure material parameter.
2. If the thermal expansion coefficient parameter is omitted, deformations resulting from thermal expansion are not considered in the bond damage calculation.
3. To get consistent results, the value should correspond to the coefficient of thermal expansion defined in the respective material model used in the block definition. To avoid double definition, the use of a variable is proposed, see 2.2.4.3.
4. The criterion only applies for bonds in tension, as the relative extension of a bond is compared to the critical stretch value, see method `computeDamage()` in `Peridigm_CriticalStretchDamageModel.cpp`. In compression the relative extension of a bond is negative and can therefore never reach the positive critical stretch value.
5. The critical stretch model is faster compared to the interface aware model, but no check if the a point is completely debonded is included. See section 3.4.4 instead.

3.4.4. Interface Aware

3.4.4.1. Description

The interface aware damage model is a critical stretch model (cf. section 3.4.2). The difference is in the implemented algorithm.

In this first pass, any "rank deficient" nodes are taken out of the linear system by pushing them into a boundary condition node set: RANK_DEFICIENT_NODES. All the bonds are broken for these nodes so it effectively removes them from the analysis. A new damage model is used to do the tasks above: Interface Aware. This model does not allow bonds to break between blocks if one of the blocks does not have a damage model. This damage model also does the checking of nodes if they meet the rank deficient criteria. A flag was also introduced that enables the user to turn off solver heuristics. For the examples tested with this commit, none of the solver heuristics were needed to get convergence. Examples have been tested that have a crack propagating through the entire domain in a single step and the solver manages to converge (if the Interface Aware damage model is used). To activate this flag, set "Disable Heuristics" to true in the solver parameters.

For the interface aware algorithm it is checked if each point has at least three bonds. If this is not the case, the point is completely disconnected. Therefore, this damage model is slower compared to the critical stretch model. However, for correspondence material this check is needed.

<td>Critical energy release rate (G_{IIIC}) [27] for compression</td>
</tr>
<tr>
<td>Type(^4)</td>
<td>string</td>
<td>✓</td>
<td>Energy Criterion</td>
<td>Interaction between Mode I and II: “Energy Criterion”</td>
</tr>
</tbody>
</table>

#### Remarks

1. The critical energy model works only for “Elastic” material, see section 3.3.2.
2. All critical energies are independent of the horizon \(\delta\).
3. If the thermal expansion coefficient parameter is omitted, deformations resulting
from thermal expansion are not considered in the bond damage calculation.

4. Interaction types:

Energy Criterion: The criterion according [27] is applied, with the assumption that the stated value for “Critical Energy Tension” corresponds to the total critical energy release rate instead of only the mode I portion.

Power Law: Mode I and II interaction by means of a quadratic power law:

\[
\left( \frac{G_I}{G_{IC}} \right)^2 + \left( \frac{G_{II}}{G_{IIIC}} \right)^2 = 1
\]

where \( G_{0C} = G_{IC} + G_{IIIC} \)

Separated: No interaction between modes. Individual energies are checked separately.

Only energies defined in the input deck are checked.

#### 3.5.1.5. List of examples

Basically all models in /test/ and /examples/.
3.6. Boundary Conditions

3.6.1. Preliminaries

3.6.1.1. Types

The following boundary condition types are defined in Peridigm:

- Prescribed Displacement
- Prescribed Fluid Pressure U
- Prescribed Temperature
- Initial Temperature
- Initial Displacement
- Initial Velocity
- Initial Fluid Pressure U
- Body Force

They are parsed in ~/src/core/Peridigm_BoundaryAndInitialConditionManager.cpp. The names are defined in ~/src/core/PeridigmEnums.cpp. The input of keywords seems to be case-insensitive.

In general only “Prescribed Displacement” can be applied in Peridigm for the application of homogeneous or inhomogeneous kinematic boundary conditions. There is no discrete command for prescribed velocities or accelerations, despite “Initial Velocity”. However, using the function parser it is still possible to apply these kinds of boundary conditions using the time variable $t$.

Generally it is possible to apply any kind of velocity $v$ or acceleration $a$ boundary conditions by considering the relationship to the displacement $u$:

\[ a(t) = \dot{v}(t) = \ddot{u}(t) \] (3.3)

3.6.1.2. Application region

Usually the boundary conditions have to be applied to particular material points for example at the free end of the body. Therefore, a nodeset has to be defined in order to list the material points to which the boundary condition has to be applied to.
If an Exodus finite element mesh is used as a discretisation the nodesets might already be defined in the mesh file. However, it is possible to define new nodesets in the Peridigm input deck as well as it is required for the discretisation via text file.

In order to define nodesets for the discretisation via a .txt file there are two options described in the next two segments

**Definition in individual text file**

*Description*

A .txt file has to be generated which contains the numbers of the desired boundary material points from the discretisation .txt file in a column.

Let the .txt files "nodeset_1.txt" and "nodeset_2.txt" be given as

<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>10</td>
<td>11</td>
<td>12</td>
</tr>
</tbody>
</table>

and define the Parameter names “Node Set One” and “Node Set Two” as

```xml
<Parameter name="Node Set One" type="string" value="nodeset_1.txt"/>
<Parameter name="Node Set Two" type="string" value="nodeset_2.txt"/>
```

Thus, the boundary condition can be applied to these particular material points by entering the name of the nodeset into the input deck section "Boundary Conditions".

**XML format**

```xml
<ParameterList name="Boundary Conditions">
  <Parameter name="Node Set One" type="string" value="nodeset_1.txt"/>
  <Parameter name="Node Set Two" type="string" value="nodeset_2.txt"/>
  <ParameterList name="Prescribed Displacement Min X Face">
    <Parameter name="Type" type="string" value="Prescribed Displacement"/>
    <Parameter name="Node Set" type="string" value="Node Set One"/>
    <Parameter name="Coordinate" type="string" value="x"/>
    <Parameter name="Value" type="string" value="0.0"/>
  </ParameterList>
</ParameterList>
```
Free format

In the free format, it is important, that the node set name ends with the term Node Set:

```
Boundary Conditions
nset_NSET-BC_BOT_SIDE Node Set "nset_NSET-BC_BOT_SIDE.txt"
  Displacement-1-D-x
    Type "Prescribed Displacement"
    Node Set "nset_NSET-BC_BOT_SIDE Node Set"
    Coordinate "x"
    Value "0.0"
```

Definition inside the model file

The other possibility to define the nodeset is to list the number of the desired nodes explicitly, i.e. as

```
<Parameter name="Node Set Three" type="string" value="2 4"/>
<Parameter name="Node Set Four" type="string" value="1 2"/>
```

The value of Parameter name can now be used as shown in the previous example.

Free format example:

```
Boundary Conditions
  Min X Node Set "1"
  Max X Node Set "2"
  Initial Velocity Min X Face
    Type "Initial Velocity"
    Node Set "Min X Node Set"
    Coordinate "x"
```
Value "1.0"
Initial Velocity Max X Face
Type "Initial Velocity"
Node Set "Max X Node Set"
Coordinate "x"
Value "-1.0"

Remarks

1. Dependent on the chosen discretisation type, a base FE mesh or the direct specification of the peridynamic collocation points in a textfile, the application region is either the finite element node id or the peridynamic collocation point id.
2. In case you use a FE mesh as discretisation type and try to define a nodeset in the model file, the base mesh node numbers do not necessarily represent the peridynamic representation collocation point numbers
3. Peridigm - Quick reference guide

3.6.2. Initial Displacement

3.6.2.1. Description

Application of a displacement at time \( t = 0 \) to the application region. For \( t > 0 \) this boundary condition is inactive.

3.6.2.2. Code

- `/src/core/Peridigm_BoundaryAndInitialConditionManager.cpp`
- `/src/core/Peridigm_BoundaryAndInitialConditionManager.hpp`
- `/src/core/Peridigm_BoundaryCondition.cpp`
- `/src/core/Peridigm_BoundaryCondition.hpp`
- `/src/core/PeridigmEnums.cpp`
- `/src/core/PeridigmEnums.hpp`

3.6.2.3. Input parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>

```xml
<ParameterList name="Boundary Conditions">
  <ParameterList name="Left Side Initial Velocity">
    <Parameter name="Type" type="string" value="Initial Velocity"/>
    <Parameter name="Node Set" type="string" value="nodelist_1"/>
    <Parameter name="Coordinate" type="string" value="x"/>
    <Parameter name="Value" type="string" value="-100.0"/>
  </ParameterList>
</ParameterList>
```

Free format

Using “Full domain” for the node set definition instead of a pre-defined node set name, from examples/fragmenting_cylinder/fragmenting_cylinder.peridigm:

```
Boundary Conditions
  Initial Velocity X
    Type "Initial Velocity"
    Node Set "Full Domain"
    Coordinate "x"
    Value "(200 - 50*((z/0.05)-1)^2)*cos(atan2(y,x))"
  Initial Velocity Y
    Type "Initial Velocity"
    Node Set "Full Domain"
    Coordinate "y"
    Value "(200 - 50*((z/0.05)-1)^2)*sin(atan2(y,x))"
  Initial Velocity Z
    Type "Initial Velocity"
    Node Set "Full Domain"
    Coordinate "z"
    Value "(100*((z/0.05)-1))"
```

YAML format

-
3.6.3.5. List of examples

- From examples/:
  - fragmenting_cylinder/fragmenting_cylinder.peridigm

- From test/regression/:
  - WaveInBar/WaveInBar.xml
3.6.4. Initial Temperature

3.6.4.1. Description

Application of a temperature at time $t = 0$ to the application region. For $t > 0$ this boundary condition is inactive.

3.6.4.2. Code

from src/core/:
- Peridigm_BoundaryAndInitialConditionManager.cpp
- Peridigm_BoundaryAndInitialConditionManager.hpp
- Peridigm_BoundaryCondition.cpp
- Peridigm_BoundaryCondition.hpp
- PeridigmEnums.cpp
- PeridigmEnums.hpp

3.6.4.3. Input parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>string</td>
<td>✓</td>
<td>-</td>
<td>“Initial Temperature”</td>
</tr>
<tr>
<td>Node Set</td>
<td>string</td>
<td>✓$^1$</td>
<td>-</td>
<td>Application region name</td>
</tr>
<tr>
<td>Value</td>
<td>string</td>
<td>✓$^2$</td>
<td>-</td>
<td>String with function for function parser</td>
</tr>
</tbody>
</table>

Remarks

1. Any string that is not “Full Domain” or “All Sets” will be considered a custom node set name in the model or mesh file, dependent of the discretization type.
2. The string in the variable Value should start with `value =`. If it does not, Peridigm will automatically add it for the function parser to work.
3. This boundary conditions might not work with some of the material models in the current implementation.

3.6.9. Body Force

3.6.9.1. Description

Application of a volumetric load to an application region.

In contrast to continuum mechanical models the peridynamic model works with the so-called force density. The force density \( F_V \) is defined as force \( F \) per volume \( V \) by \( F_V = F/V \). The dual or pairwise force density function as an internal variable is then defined as force per volume squared (see page 14 in [29]). External forces on the peridynamic collocation points are expressed in the bond force density. The bond force density has the unit force per unit squared as well. Thus, the nodal, surface and volume loads from continuum mechanics can easily be transformed using the application region volume.

However, one has to consider that the force density is applied for the whole volume. The resulting displacements are given at the points. Therefore, there are small discrepancies in the position of the applied load in peridynamics compared to the discretized continuum mechanics model.

3.7. Contact

3.7.1. General options

3.7.1.1. Description

Define contact for the model. Contact forces in Peridigm are not applied for nodes that are bonded. This avoids the situation where two nodes interact via both contact and the constitutive model.

> From David Littlewood:

- Be aware also that the input deck syntax for contact is not representative of what’s actually in the code. [...] As far as I remember, what’s actually implemented in Peridigm is a all-to-all contact model that is active for any pair of nodes that are not bonded to each other. So, there is no consideration of blocks, node sets, etc., and basically both self contact and general contact are always on.

- The portion of the input deck in which contact interactions are specified is not currently functional. Contact only operates in two modes: either completely off, or on for everything. By “on for everything” I mean that every node interacts with every other node, regardless of material block or what is specified in the input deck. This is obviously not ideal and is confusing to users. The contact portion of the code underwent a significant refactor a few years ago. A good deal of progress was made with respect to performance and I/O, but unfortunately the code ended up in a partially refactored state. One part that was not completed is user-defined per-block contact interactions. The parsing was set up but the internal logic was not implemented. The contact code in general needs significant work IMHO.

> From James O’Grady:

Nodes that are initially bonded will never interact via the contact model, even after the bond between them is broken. I’m not sure whether that includes bonds broken by a pre-crack.

3.7.1.2. Code

Release version

Available from version 1.2.
Required compiler options

-

Routines

→ /src/core/Peridigm_ContactManager.cpp
→ /src/core/Peridigm_ContactManager.hpp

3.7.1.3. Input parameters

3.7.2. Models

3.7.2.1. Short Range Force

Description

A simple contact model for the interaction of non-bonded elements.

⇒ From David Littlewood:
   To the best of my knowledge, the short-range contact model in Peridigm is completely ad hoc. It isn’t tied to anything physical as far as I know, and I’m not aware of any general usage rules. It’s just a repulsive force that was implemented to give somewhat reasonable results for impact problems.

Literature

⇒ [6]
⇒ [1]

Code

Release version

Available from version 1.2.

Required compiler options

-

Routines

⇒ /src/contact/Peridigm_ShortRangeForceContactModel.cpp
⇒ /src/contact/Peridigm_ShortRangeForceContactModel.hpp

**Input parameters**

**List**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contact Model</td>
<td>string</td>

<td>✓</td>
<td>0.0</td>
<td></td>
</tr>
<tr>
<td>Horizon$^5$</td>
<td>double</td>
<td>✓</td>
<td>0.0</td>
<td></td>
</tr>
</tbody>
</table>

**Remarks**

1. Contact algorithm operates on planar facets, these are created from peridynamic collocation points, see [30] & [15]
2. Initial guess for contact radius: somewhat smaller than the initial node spacing, so that it doesn’t add forces to material in the undeformed or slightly deformed configuration. I would also expect it to be large enough to prevent material interpenetration.
3. From David Littlewood: The spring force parameter is determined by trial and error, although a good initial guess might be 10 times the force of the constitutive model.
4. In case Friction Coefficient is not defined, no friction is applied by using the default value
5.

3.8. Compute Class Parameters - User defined calculation data

3.8.1. Compute Class Parameters for node sets

3.8.1.1. Description

Define user defined calculation data for nodesets. These quantities can later be output, see section 3.11.3.

3.8.1.2. Code

- /src/compute/Peridigm_Compute_Node_Set_Data.cpp
- /src/compute/Peridigm_Compute_Node_Set_Data.cpp

3.8.1.3. Input parameters

List

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute Class</td>
<td>string</td>
<td>✓</td>
<td></td>
<td>“Node_Set_Data”</td>
</tr>
<tr>
<td>Calculation Type</td>
<td>string</td>
<td>✓</td>
<td>-</td>
<td>“Minimum”</td>
</tr>
<tr>
<td>Node Set</td>
<td>string</td>
<td>✓</td>
<td>-</td>
<td>Node set name</td>
</tr>
<tr>
<td>Variable</td>
<td>string</td>
<td>✓¹,³</td>
<td>-</td>
<td>Output variable</td>
</tr>
<tr>
<td>Output Label</td>
<td>string</td>
<td>✓²</td>
<td>-</td>
<td>Output label for output section</td>
</tr>
</tbody>
</table>

Remarks

1. The output value identifier are defined in src/io/mesh_output/Field.h. Possible values are defined in subsubsection 3.11.1.1.
2. For the output to have any effect, the output label must be defined in the “Output” section of the input deck.
3. The item requested as Variable must be defined and requested as a global Output Variable in the Output block, e.g.: In case you request a Compute Class Parameter Top Reaction Force with Variable “Force”:
Compute Class Parameters
   Top Reaction Force
     
     Variable "Force"
     Output Label "Top_Reaction_Force"

Than Force ‘true’ must be defined in the Output section:

Output
   Output File Type "ExodusII"
     
     Output Variables
     
     Block_Id "false"
     
     Force "true"
     Top_Reaction_Force "true"

Without Force ‘true’ an error is thrown as the group variables cannot be extracted from the global solution.

4. There seems to be a bug in the text file reader in case nodesets are defined by additional text files for the text file discretization from 2.3.2. There are two possible workarounds:

   a) Use the python script `text_to_genesis.py` to convert your text file into a genesis file. This script is in the scripts directory of the Peridigm repo, you probably will have to edit the PATH at the top of the python file to point to your Trilinos lib directory so it can load exodus.py.

   b) If possible, create an individual block for the domain of the nodeset and use the compute class parameter option for blocks from 3.8.2

3.8.1.4. Exemplary input section

XML-format

from test/regression/Contact_Ring/Contact_Ring.xml:

```xml
<ParameterList name="Compute Class Parameters">
   <ParameterList name="Node Set 10 Stored Elastic Energy">
      <Parameter name="Compute Class" type="string" value="Node_Set_Data"/>
      <Parameter name="Calculation Type" type="string" value="Sum"/>
      <Parameter name="Node Set" type="string" value="nodelist_10"/>
   </ParameterList>
</ParameterList>
```
Free format

YAML format

  - Contact_Ring/Contact_Ring.xml
  - WaveInBar_MultiBlock/WaveInBar_MultiBlock.xml
3.8.2. Compute Class Parameters for blocks

3.8.2.1. Description

User defined output for blocks using Compute Class Parameters. These quantities can later be output, see section 3.11.4.

3.8.2.2. Code

- /src/compute/Peridigm_Compute_Block_Data.cpp
- /src/compute/Peridigm_Compute_Block_Data.hpp

3.8.2.3. Input parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute Class</td>
<td>string</td>
<td></td>
<td></td>
<td>&quot;Block_Data&quot;</td>
</tr>
<tr>
<td>Calculation Type</td>
<td>string</td>
<td></td>
<td></td>
<td>&quot;Minimum&quot;</td>
</tr>
<tr>
<td>Block</td>
<td>string</td>
<td></td>
<td></td>
<td>Block name</td>
</tr>
<tr>
<td>Variable</td>
<td>string</td>
<td>✓, 1, 3</td>
<td></td>
<td>Output variable</td>
</tr>
<tr>
<td>Output Label</td>
<td>string</td>
<td>✓, 2</td>
<td></td>
<td>Output label for output section</td>
</tr>
</tbody>
</table>

Remarks

1. The output value identifier are defined in src/io/mesh_output/Field.h. Possible values are defined in subsubsection 3.11.1.1.
2. For the output to have any effect, the output label must be defined in the “Output” section of the input deck. This is necessary since the Compute Class Parameters are extracted from the global solution/output data.
3. The item requested as Variable must be defined and requested as a global Output Variable in the Output block, e.g.: In case you request a Compute Class Parameter Top Reaction Force with Variable "Force":

```
Compute Class Parameters
Top Reaction Force
...                        
Variable "Force"
```
Output Label "Top_Reaction_Force"

Than Force "true" must be defined in the Output section:

Output
  Output File Type "ExodusII"
  ..
  Output Variables
    Block_Id "false"
    ...
    Force "true"
    Top_Reaction_Force "true"

Without Force "true" an error is thrown as the group variables cannot be extracted from the global solution.

       - NeighborhoodVolume/NeighborhoodVolume.xml
       - SurfaceFactorCube/SurfaceFactorCube.xml
3.9. Solver

3.9.1. Preliminaries

Peridigm supports various solver which basically represent different time integration schemes. The solver definition consists of two steps:

1. Definition of initial and final time
2. Specification of the time integration scheme

The specification of the time integration scheme is a sublist of parameters in the solver definition.
3.9.2. Explicit - Verlet

3.9.2.1. Description

Solver with explicit time integration.

Velocity-Verlet (leapfrog), keyword Verlet, is a time integration scheme for explicit dynamics [31]. Peridigm will automatically estimate a safe stable timestep for your problem. The Safety Factor multiplies this estimate. You can override the max stable timestep computed by Peridigm by specifying a timestep manually.

3.9.2.2. Code

```
/sr/core/Peridigm.cpp
  → PeridigmNS::Peridigm::execute
  → PeridigmNS::Peridigm::executeExplicit
/sr/core/Peridigm.hpp
```

3.9.2.3. Input parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solver parameters</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Initial Time</td>
<td>double</td>
<td>-</td>
<td>0.0</td>
<td>Start time of simulation</td>
</tr>
<tr>
<td>Final Time</td>
<td>double</td>
<td>✓</td>

<td>Multiply stable timestep estimate returned by Peridigm by the user-supplied safety factor</td>
</tr>
<tr>
<td>Numerical Damping(^2)</td>
<td>double</td>
<td>-</td>
<td>0.0</td>
<td>adds a numerical damping to the time integration to stabilize the dynamics caused by cracks</td>
</tr>
</tbody>
</table>

\(^1\)Implemented by DLR

\(^2\)Implemented by DLR
Remarks

1. Fixed dt and Safety Factor are mutually exclusive.
2. Specification of a timestep larger than the stable time step or a safety factor greater than one may cause instable solutions.

3.9.2.4. Exemplary input section

XML-format

```xml
<ParameterList name="Solver">
  <Parameter name="Verbose" type="bool" value="false"/>

<td></td>
</tr>
<tr>
<td>Absolute Tolerance</td>
<td>double</td>
<td>-</td>
<td>$\sqrt[3]{3}$</td>
<td>Convergence criteria for the residual.</td>
</tr>
</tbody>
</table>

**Remarks**

1. Since the analysis is quasi-static, the values of Initial Time and Final Time are irrelevant.
2. Two types of load step input are mutually exclusive, but one of them is required in the definition:
   - Final Time and Number of Load Steps
   - Time Steps
3. A default value is calculated. In case of convergence problems, increase the value of Absolute Tolerance.

3.9.5. NOXQuasiStatic (nonlinear)

3.9.5.1. Description

NOX Quasi-static, keyword NOXQuasiStatic, is a time integration scheme for quasi-static analysis using a nonlinear solver with modified Newton approach using the NOX solver from Trilinos. NOX is short for Nonlinear Object-Oriented Solutions, and its objective is to enable the robust and efficient solution of the equation: $F(x) = 0$, where $F: \mathbb{R}^n \rightarrow \mathbb{R}^n$. NOX implements a variety of Newton-based globalization techniques including Line Search and Trust Region algorithms. In addition it provides higher and lower order models using Broyden and Tensor algorithms. Special algorithms have been developed for use with inexact linear solvers such as Krylov subspace techniques. NOX is designed to work with any linear algebra package and to be easily customized.

- Newton-Based Nonlinear Solver
  - Linked to Trilinos linear solvers for scalability
  - Matrix-Free option
- Anderson Acceleration for Fixed-Point iterations
- Globalizations for improved robustness
- Line Searches, Trust Region, Homotopy methods
- Customizable: C++ abstractions at every level
- Extended by LOCA package (Parameter continuation, Stability analysis, Bifurcation tracking)

- Download: Part of Trilinos
- Further information: Andy Salinger agsalin@sandia.gov

- From test/regression/:
  - Contact_Perforation_Run1.xml
  - Contact_Perforation_Run2.xml
3.11. Output

3.11.1. Preliminaries

Basically, there are five types of distinguished output data in Peridigm:

- Global scalar fieldspecs
- Multiphysics fieldspecs
- Element scalar fieldspecs
- Nodal Vector3D fieldspecs
- Bond scalar fieldspecs

scalar fields defined over entire simulation
scalar fields defined over elements
vector fields defined at nodes

All identifiers for possible output values are defined in \src\io\mesh_output\Field.h.

3.11.1.1. Output variables

Global scalar

- Global_Angular_Momentum
- Global_Kinetic_Energy
- Global_Linear_Momentum
- Global_Strain_Energy
- Global_Strain_Energy_Density

Multiphysics

Not considered here.

- Fluid_Pressure_U
- Fluid_Pressure_V
- Fluid_Pressure_Y
- Flux
- Flux_Density

Element scalar

- BC_MASK
- Block_Id
- Critical_Stretch
- Critical_Time_Step
- Damage
- Density
- Dilatation
- Element_Id
- Interface_Proximity
- Kinetic_Energy
- Lambda
- Neighborhood_Volume

DLR – DLR-IB-FA-BS-2018-23
3. Peridigm - Quick reference guide

- Norm_td
- Num_Neighbors
- Number_Of_Neighbors
- Proc_Num
- Radius
- Strain_Energy
- Strain_Energy_Density
- Volume
- Weighted_Volume

**Nodal Vector3D**

- Acceleration
- Angular_Momentum
- Contact_Force
- Contact_Force_Density
- Coordinates
- Displacement
- Force
- Force_Density
- Linear_Momentum
- Model_Coordinates
- Residual
- Tangent_Reference_Coordinates
- Velocity

**Bond scalar**

- Bond_Damage
- Deviatoric_Plastic_Extension
- Deviatoric_Back_Extension
- Partial_Volume

The different entities are written to different output files:

- .e: Element scalar, Nodal Vector3D, Bond scalar
- .h: Global scalar

It is not differentiated between cellular data and point data. Also it is not important if the calculation supports the output. If the simulation has no results for a specific output the data will be set to zero. However, the size of the output file itself is influenced. All variables can be found with the defined names in Paraview.

**Additional output values from classes**

The following classes have their own output values. The specific output variables are stated in the class description in this document.

- Materials
- Compute classes in src/compute/
Compute class output values

- Stored_Elastic_Energy.cpp
- Stored_Elastic_Energy_Density.cpp
3.11.1.2. Output data acquisition

Output data acquisition basics

The output data acquisition block starts with information about how and where to store the entities. The following entries are not mandatory:

- Output Format: default: binary
- Parallel Write: default: true

Output data acquisition without global scalar entities

In case no global scalar value is required, it is sufficient to create one output in the input deck. OUTPUT PARAMETER LIST can contain any of the aforementioned entities for the .e-results file. By default the output is set to false for all entities. The result file will be FILENAME.e.

Free-format

```
Output
  Output File Type ExodusII
  Output Format "Binary"
  Output Filename "FILENAME"
  Output Frequency "1"
  Parallel Write "true"
  Output Variables
    OUTPUT PARAMETER LIST, e.g.
    Displacement "true"
    Velocity "true"
```

XML-format
Output data acquisition including global scalar entities

Two different sets of outputs have to be created, one for the .e- and one for the .h-entities. The result files will be FILENAME.e for Output_1 and FILENAME.h for Output_2. The output frequencies can vary between the two outputs. The non-mandatory items are left out in this example.

Free-format

Output1
Output File Type ExodusII
Output Filename "FILENAME"
Output Frequency "10"
Output Variables
  .e OUTPUT PARAMETER LIST, e.g.
  Displacement "true"
  Velocity "true"

Output2
Output File Type ExodusII
Output Filename "FILENAME"
Output Frequency "5"
### Output Variables

- .h OUTPUT PARAMETER LIST, e.g.
  - Global_Kinetic_Energy "true"
  - Global_Linear_Momentum "true"

**XML-format**

**equivalent**
3.11.1.3. Output sequence

A sequentially different output, e.g. for different solver steps, can be obtained via the specification of Initial Output Step and Final Output Step for each Output block. For the first output block Initial Output Step and for the last output block Final Output Step do not have to be specified if these coincide with 0.0 and the end of the simulation.

Exemplary input section

XML-format

```
Output1
Output File Type "ExodusII"
Output Format "BINARY"
Output Filename "model_implicit"
Output Frequency 1
Final Output Step 10
Output Variables
  Block_Id "true"
  ... Displacement "true"
```

```
Output2
Output File Type "ExodusII"
Output Filename "model_explicit"
Output Frequency 50
Initial Output Step 11
Output Variables
  Block_Id "true"
  ...
```
Displacement "true"

4. Run *Peridigm*

4.1. Execution

4.1.1. On a local machine or a virtual box

4.1.1.1. Input

*Peridigm* is run from the command line and requires both an input deck (text file) and a discretization. Input decks may be in either of the formats described in section 2.2.

*Peridigm* is capable of operating on several types of discretizations. The different types of discretizations are described in section 2.3.

An example command for running *Peridigm* from the command line:

```
Peridigm my_input.peridigm
```

*Peridigm* is meant to be run in a massively parallel setting. In order to use multiple processors in combination with *Exodus/Genesis* mesh files (*.g) parallel decomposition of these files has to performed first as a pre-processing step when running multi-processor *Peridigm* simulations. The `decomp` utility, provided by the *SEACAS Trilinos* package, provides a mechanism for decomposing an *Exodus/Genesis* mesh file. An example command for partitioning an *Exodus/Genesis* mesh file with `decomp` for four processors:

```
de comp -p 4 my_mesh.g
```

If the `decomp` tool is not available in the PATH variable use:

```
/usr/local/bin/trilinos-12.4.2/bin/decomp -p 4 my_mesh.g
```

Afterwards, *Peridigm* can be run in parallel with the same amount of threads with:

```
mpirun -np 4 Peridigm my_input.peridigm
```

Text file discretizations do not require this pre-processing step, they are partitioned automatically by *Peridigm*. 
4. Run Peridigm

4.1.1.2. Output

Preliminary informations

Peridigm generates output in the Exodus file format. The content of an Exodus output file is dictated by the Output section of a Peridigm input deck. Output may include primal quantities such as nodal displacements and velocities, as well as derived quantities such as stored elastic energy. The ParaView visualization code is recommended for viewing Peridigm results. Additional options for parsing output data are available within the SEACAS Trilinos package.

Exodus is based upon NetCDF-C, and also includes the nemesis parallel extensions. Exodus is fundamentally a serial output format, and each MPI process will open and write its own Exodus database for all the elements that it owns. If a load rebalance occurs during the course of a parallel simulation, each MPI process must close its Exodus database and open a new database containing the elements owned by that process after the rebalance. The net effect is that many Exodus output files may be generated during the course of a parallel simulation. Tools in the SEACAS package to help in merging these separate files together into a single Exodus database.

Merge result files of MPI executions of Peridigm

To automate the merging of result files for MPI executions of Peridigm, a python script is distributed with Peridigm. The file is located in ../scripts/MergeFiles.py of the Peridigm installation directory. This script will produce a single Exodus database file containing the complete simulation output.

Before you can access the script you have to add read and execution rights to the Peridigm folders as root:

```bash
chmod -R go+rx /usr/local/src/Peridigm-1.4.1*
```

To use the script, create a symbolic link in the model directory, where the individual output files in the Exodus format are located:

```bash
ln -sf /usr/local/src/Peridigm-1.4.1/scripts/MergeFiles.py
```

Afterwards, execute the script with the number of processors and the model name as parameters.

```bash
./MergeFiles.py <File Base Name> <# of Processors>
```
For the `fragmented_cylinder.peridigm` example from the `Peridigm` examples directory and an initial calculation using four processors, the call to the script is

```
./MergeFiles.py fragmented_cylinder 4
```

which merges the result files `fragmented_cylinder.e.0...fragmented_cylinder.e.3` of each individual processor to `fragmented_cylinder.e`. This is the final results file and should be used for postprocessing in `ParaView`.

### 4.1.1.3. Examples

The most effective way to learn how to use `Peridigm` is to run the example problems in the `Peridigm/examples/` directory. These simulations were designed to highlight the most commonly-used features of `Peridigm`, including constitutive models, bond-failure rules, contact, explicit and implicit time integration, and I/O commands.
4. Run Peridigm

4.1.2. On the STM-Cluster

First, read the previous section and the cluster documentation carefully. Login to the cluster afterwards.

4.1.2.1. Run the official release version

Obsolete

To split the model for an MPI-run of Peridigm using decomp the Peridigm environment has to be loaded with

```
. /cluster/software/slurm/etc/env.d/peridigm.sh
```

Afterwards, all commands for the execution of Peridigm and the required tools are available in this shell.

The cluster uses a queue-system and you need to add your Peridigm-run to the queue. All cluster queuing commands are applicable to Peridigm. To add a Peridigm-job to the queue use one of the following possibilities:

1. Call Peridigm on an arbitrary node with a specified number of threads/tasks ($NRTHREADS) and calculate the input file ($INPUTFILE):

   ```
   qperidigm -d -c $NRTHREADS $INPUTFILE
   ```

   e.g.
   ```
   qperidigm -d -c 16 input.peridigm
   ```

2. Call Peridigm on a specific node ($NODE) exclusively, which uses all threads/tasks of this node, and calculate the input file ($INPUTFILE):

   ```
   qperidigm -d -w $NODE -X $INPUTFILE
   ```

   e.g.
   ```
   qperidigm -d -w node1 -X input.peridigm
   ```

After the analysis is completed, the result files have to be merged. To make the merge script available, type
4. Run Peridigm

```bash
./cluster/software/slurm/etc/env.d/peridigm.sh
```

if you do not use the same shell as for the decomposition of the mesh. Use the merge
script as in the previous section:

```bash
MergeFiles.py <File Base Name> <# of Processors>
```

Current

Everything described in the previous section is included now in the cluster command
`qperidigm`. The decomposition of the mesh as well as the merging of the results file
is done automatically.

To execute a job with `NRTHREADS` threads simply type:

```bash
qperidigm -c $NRTHREADS input.peridigm
```

4.1.2.2. Run a locally built Peridigm version

For instruction how to locally compile and install a Peridigm version check the Peridigm
Installation Guide from the repository. To use this local version in the queuing-system, here
`~/src/peridigm/build/src/Peridigm`, use the `-E` option during the call to `qperidigm`,
e.g.:

```bash
qperidigm -d -X -c 32 -E ~/src/peridigm/build/src/Peridigm $INPUTFILE
```
4.2. Best practices

4.2.1. Bridge “time” until failure occurs

For stability reasons it is currently beneficial to calculate the damage behavior of a structure using the explicit solver. Dependent on the material properties and loads, the model has to sustain a certain amount of displacement before initial failure occurs. The solution domain is commonly of little interest. Thus, some ways are proposed to get to the state where failure occurs faster.

4.2.1.1. Use a combination of multiple solvers

Use a sequence of a quasi-static and an explicit solver as described in subsection 3.9.6. This way might not be possible in case the model and therefore stiffness matrix is too large for the computational hardware. In this case, the tangent stiffness matrix cannot be allocated for the quasi-static solver. Instead, the idea proposed in the next section can be applied.

4.2.1.2. Use an initial displacement

If a continuous displacement field is present before failure, e.g. bridging the gap between an impactor and the structure or a uniform tensile test, an initial displacement can be applied on the collocation point nodes of the complete moving structure. It is not possible to just apply the initial displacement on the boundary condition region. If the initial displacement is larger than the horizon, the model will fall apart.

To get the correct offset

```
OFFSETORIGINX=-23.0/2.0
FAILUREDISPLACEMENTINIT=0.900
FAILUREDISPLACEMENTFINAL=1.100
...
Boundary Conditions
...
InitialDisplacement-3-D-x
  Type "Initial Displacement"
  Node Set "moving_x"
  Coordinate "x"
```
4. Run Peridigm

Value "value={FAILUREDISPLACEMENTINIT}*(x-{OFFSETORIGINX})"

Displacement-1-V-x
  Type "Prescribed Displacement"
  Node Set "bc_load"
  Coordinate "x"
  Value "value={FAILUREDISPLACEMENTINIT}+{VELOCITY}*t"

... Solver
  Verbose "true"
  Final Time \{\text{(FAILUREDISPLACEMENTFINAL-FAILUREDISPLACEMENTINIT)}/\text{VELOCITY}\}
  Verlet
  Safety Factor 0.9
4.2.2. Increase timestep in explicit solver

The critical time step calculation is performed in the `PeridigmNS::ComputeCriticalTimeStep` method in the class `/src/core/Peridigm_CriticalTimeStep.cpp`. The calculation is carried out for each block as requested in `PeridigmNS::Peridigm::executeExplicit` of `src/core/Peridigm.cpp`. The minimum of all block values is taken as the final critical time step.

The equation used for the determination of the critical time step is

\[
\Delta t_{\text{Block}} = \sqrt{\frac{2\rho}{\Delta t_{\text{Denominator}}}} \quad (4.1)
\]

The time step denominator itself is a function of the collocation point volume, neighbor distance and “bond” stiffness. Despite implementing the state-based peridynamics, Peridigm uses the bond constant for 3D bond-based peridynamics from Table 2.3 as the the “bond” stiffness. Thus

\[
\Delta t_{\text{Denominator}} = f(\Delta x, K, \delta^{-4}) \quad (4.2)
\]

The following actions can be taken to influence the time step:

- **Increase material density**
  - For quasi-static simulations a certain amount is possible
  - Reduces oscillation effects due to increased mass inertia
  - Limit is aperiodic boundary case

- **Increase element size**:  
  - A larger element size increases the volume associated with each peridynamic collocation point  
  - On the other hand the initial distance between points is increased  
  - Thus, do not expect a linear response of the time step for changing mesh sizes

- **Increase horizon**
4. Run Peridigm

4.2.3. Create pre-cracks

See subsection 3.2.2

I suggest you output the variable Number_Of_Neighbors in your output file, so that you can confirm that your pre-crack is in the right place. It always seems to take me multiple tries to get it right.
5. Pre- and postprocessing with *ParaView*

5.1. Input & Import

*Peridigm* creates result files in the *Exodus* format. This format can read by *ParaView*. It is basically the same format as the *Exodus* finite element mesh discretization. Therefore, also the underlying *Exodus* mesh can be visualized in *ParaView*.

If multiple processors are used for the execution of *Peridigm* each MPI core creates an individual *Exodus* output file. The individual result files must be merged before the output can be used in *ParaView*. For the proper procedure please consult section 4.1.1.2.

To import a file to *ParaView* perform the following steps

1. From the menu bar:
   - Click File
   - Click Open
   - Select the .g/.e-*Peridigm* input or output file

   or click 📛 in the Main Controls toolbar

2. In the newly opened Properties tab:
   - Choose the variables you want to use for post-processing
   - Choose the blocks, assemblies and material regions you want to include
   - Click Apply
5. Pre- and postprocessing with ParaView

5.2. Result data

ParaView distinguishes three types of result data:

- point data
- cell data
- field data

Point data is specified at each grid point. Cell data is specified per cell. Field data occurs for user-defined output values. Several linear and non-linear cell types currently exist for one-, two- or three-dimensional applications. E.g. a cell can be a quadrilateral between four nodes in two dimensions, a hexahedron volume between eight nodes in three dimensions or others. All cell types are shown in [32].

Following is a list of Peridigm post-processing items and their classification as point data or cell data.

- Point data results:
  - Contact_Force
  - Displacement
  - Force
  - Global Node Ids
  - Velocity
  - ...

- Field data results:
  - Compute Class Parameter results

- Cell data results:
  - Damage
  - Dilatation
  - Element_Id
  - Global Element Ids
  - Number_Of_Neighbors
  - Object IDs
  - Proc_num
  - Radius
  - Weighted_Volume
  - ...

DLR – DLR-IB-FA-BS-2018-23
5.3. Selection

5.3.1. Create a selection

Selections are

- a mechanism to identify subset of a dataset
- Focus on selected subset:
  - Inspect properties of the subset
  - Further process subset alone
- Track subset over time

Selections are performed in a toolbar in the RenderView. At first it has to be chosen if the items should be added to or removed from the selection using the following buttons:

- Add selection
- Subtract selection
- Toggle selection

In a second step the kind of item, cells or points, to be selected has to be specified:

Points:
- Select points on
- Select points through
- Select points with polygon
- Select points interactive

Cells:
- Select cells on
- Select cells through
- Select cells with polygon
- Select cells interactive

Selection steps can be repeated as long as no Filter dependent on the selection is active. The currently selected entities are highlighted.

5.3.2. Limit display to selection

To limit the model to a user defined selection:

1. Import result file to ParaView
2. Create a selection
3. From the menu bar:
   - Click Filters
   - Click Data Analysis
   - Click Extract Selection
   or click in the Data Analysis toolbar
4. Click Apply in the newly opened Properties tab
5.3.3. Remarks

1. Selected points lie in a virtual box. If the deformation of the model are to big, the points move outside the box and the allocation is lost. This might be an issue for plotting data. This can be solved by setting the deformation scaling to zero.
5. Pre- and postprocessing with ParaView

5.4. View & Display

5.4.1. Save view

To save a view configuration click on the Adjust Camera button 🎥 in the icon bar of your RenderView.

5.4.2. Display point/node numbers

After importing the model it might be of interest to get the node/point numbers for the whole model or a specific selection. To show these numbers after importing the model:

1. Generate and extract the selection of interest according to section 5.3
2. Left-click on the imported model (set the model active)
3. From the menubar:
   - Click View
   - Click Selection Display Inspector
4. In the Selection Display Inspector window:
   - Click on Point Labels
   - Select ID
5. The point/node numbers appear as labels

5.4.3. Visualize nodesets

To visualize the nodesets from a Exodus mesh or Peridigm results file in ParaView perform the following steps

1. From the menu bar:
   - Click File
   - Click Open
   - Select the .g/.e-Peridigm input or output file
   or click 🗂️ in the Main Controls toolbar
2. In the newly opened Properties tab:
   - Click the gear symbol 🏭️ next to the Search line
   - Sets and Maps tables become available for selection

DLR – DLR-IB-FA-BS-2018-23
5. Pre- and postprocessing with ParaView

Figure 5.1.: Display of selection point/node numbers

- Select the nodesets to display
- Unselect all Blocks
- Click Apply

3. Create a Glyph based on the current model as described in subsection 5.4.4 (without the result data stuff of course)

4. Repeat step 1

5. In the newly opened Properties tab:
   - Select all Blocks
   - Set the Opacity to 0.4
   - Click Apply

Similarly, the nodesets in the peridynamic collocation point translation can be visualized. The following figure shows the base Exodus finite element mesh in gray. Superimposed with the finite element mesh are the nodes of a finite element nodeset (blue) and the nodeset in the peridynamic translation (green).
5. Pre- and postprocessing with ParaView

Figure 5.2.: Visualization of base finite element mesh (gray), finite element node-set (blue) and nodeset after transformation to peridynamic collocation points (green)

5.4.4. Damage plot on nodes as spheres

Commonly, the Peridigm results are plotted on so called Glyphs in ParaView. A Glyph is a geometric object with a specific size, a direction and a color, which is drawn at certain positions within the vector field. Glyph shapes can be an

- Arrow
- Cone
- Box
- Cylinder
- Line
- Sphere
- 2D glyph

A natural choice for peridynamic nodes is the sphere. Unfortunately, cell data can not be plotted directly in a Glyph plot. Therefore, the cell data has to be converted to point data first.

1. Import result file to ParaView
2. Left-click on the result file once in the Pipeline Browser (mark the result file)
3. From the menu bar:
   - Click Filters
   - Click Alphabetical
   - Click Cell Data to Point Data
4. Left-click on the new item *Cell Data to Point Data* in the Pipeline Browser

5. From the menu bar:
   - Click Filters
   - Click Common
   - Click *Glyph*

   or choose the *Glyph*-symbol from the common filter icon toolbar

6. In the *Glyph* properties window choose:
   - Glyph Type: *Sphere*
   - Scalars: *Damage*
   - Vectors: *Displacement*
   - Scale factor: Choose according to your needs
   - Glyph mode: *All Points*
   - Coloring: *Damage*

   and click *Apply*

7. Afterwards, return to the properties window, go to the *Display* section and choose:
   - Representation: *Surface*
   - Coloring: *Damage*

Afterwards, you can skip through the time steps of your analysis in the Current Time Controls toolbar. It maybe necessary to adjust the range of the legend to the current time step minimum or maximum.
5. Pre- and postprocessing with ParaView

5.5. Plotting

5.5.1. Plot selection data over time

To plot selection data, e.g. point results, over calculation time perform the following steps:

1. Import result file to ParaView
2. Create a selection, e.g. to a single or two points
3. From the menu bar:
   - Click Filters
   - Click Data Analysis
   - Click Plot Selection Over Time
   or click in the Data Analysis toolbar
4. In the newly opened Properties tab:
   - Review the Copied Selection
   - Click Apply
   - Let ParaView process your request a couple of seconds
   - For the actual values deselect the Only Report Selection Statistics checkbox
   - Click Apply
   - Wait until the progressbar in the bottom right is completed
   - Select from the selection entities the items you are currently interested in
   - Choose the Series Parameters you are interested in (there is the same quantity for each selection entity, so a couple of times if you have multiple entities in your selection, choose wisely)
   - Your requested values should show up in the QuartileChartView

5. You can skip through the time steps of your analysis in the Current Time Controls toolbar. The current time is shown as the vertical bar in the chart view

To see the actual values in a spreadsheet:

1. Right-click on the QuartileChartView top line (where e.g. QuartileChartView1 stands)
2. Create a selection, e.g. to a single or two points
3. Select:
   - Convert To ...
   - Spreadsheet view

4. In case you want to return to the Chart View you can do so accordingly but you have to repeat the data selection steps mentioned above
Figure 5.3.: Combined ParaView view

A combined view:

To save the data for plotting in pgfplots:

1. Select the PlotOverSelection in the Pipeline Browser or left click in the ChartView or SpreadsheetView
2. From the menu bar:
   - Click File
   - Click Save Data
   or click 🔄 in the Main Controls toolbar
3. Select folder and filename
4. Select csv file type
5. Click Ok

Beware, an individual csv-file is written for each and every entity in your selection. The file does not include any information on the entity ID or name. Thus, a sequential save-process for each single individual entity is advised. After each save, rename the resulting file.
5.5.2. Force-displacement-plots

5.5.2.1. General

This plot shows the course of the “nodal” force in a constrained region of the model over the displacement of a discrete point. The sum of the forces is used as a representative of the integral force value a load cell would show. For the displacement the value of a discrete node or collocation point is used as a representative for the scalar value of an extensiometer or the machine displacement value.

5.5.2.2. Peridigm/ParaView

Requisition of output values in Peridigm

To acquire forces and displacements for a defined part of a model Compute Class Parameters are used in Peridigm. They are described in sections 3.8.1, 3.8.2 & 3.8.3. The forces are requested for the node set or block where a body load or in this case boundary condition is applied on. The displacement is written for one point in this node set using the nearest neighbor approach to a defined spatial coordinate in the node set region. The initial position of the point the displacements are written for is also requested for convenience and checks.

<table>
<thead>
<tr>
<th>Compute Class Parameters</th>
<th>Strain Gage Initial Position</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Compute Class &quot;Nearest_Point_Data&quot;</td>
</tr>
<tr>
<td></td>
<td>X 0.0317</td>
</tr>
<tr>
<td></td>
<td>Y 1.238</td>
</tr>
<tr>
<td></td>
<td>Z 0.0</td>
</tr>
<tr>
<td></td>
<td>Variable &quot;Model_Coordinates&quot;</td>
</tr>
<tr>

</tr>
</tbody>
</table>

Reaction Force
5. Pre- and postprocessing with ParaView

Compute Class "Node_Set_Data"
Calculation Type "Sum"
Node Set "bc_load"
Variable "Force"
Output Label "Reaction_Force"

Alternatively, it should also be possible to request the displacement for the same node set as the force and simply choose “Minimum” or “Maximum” as Calculation type. This way, it is not required to adjust the spatial coordinates as in Compute Class “Nearest_Point_Data”. This works fine for a test case.

Additionally the global output variable types Displacement and Force must be requested in the output section.

Output:
Output File Type "ExodusII"
Output Filename "model"
Output Frequency 1
Output Variables
  ... Displacement "true"
  ... Force "true"
  ...
  Gage_Initial_Position "true"
  Gage_Displacement "true"
  Reaction_Force "true"

Access result data in ParaView

1. Make sure that the requested result data from the Compute Class Parameters is available in your results file. If you are only interested in these parameters, unselect all other.
2. Add a new view & select Spreadsheet View
3. For Showing select your model and for Attribute select Field Data
4. Click to select the columns of interest
5. Click to save the spreadsheet data as a csv-file
   a) Specify a filename & click Ok
   b) In the next dialog toggle Filter Columns by Visibility. Otherwise, all data is written to the csv-file.
6. Do with the data whatever you want

**Plot result data directly in ParaView**

1. Import your model
2. Make sure that the requested result data from the *Compute Class Parameters* is available in your results file. If you are only interested in these parameters, unselect all other.
3. From the menu bar:
   - Click Filters
   - Click Alphabetical
   - Click *Cell Data to Point Data*
4. Select points of interest:
   - Select the *Cell Data to Point Data* entry in the Pipeline Browser
   - Create a new selection of a single or multiple points in your constraint region as described in subsection 5.3.1
   - Extract the selection as described in subsection 5.3.2
5. From the menu bar:
   - Click Filters
   - Click Data Analysis
   - Click *Plot Selection Over Time*
   or click ![image](image-url) in the Data Analysis toolbar
6. Preferences in the *Properties* window
5. Pre- and postprocessing with ParaView

5.5. Plot Compute Class Parameters results data in ParaView

- Under X Axis Parameters select your displacement component or magnitude from the Compute Class Parameters in the X Array Name combobox
- For Series Parameters select the force value you want to plot from the Compute Class Parameters, either as a component or magnitude
- Input a Left Axis Title and Bottom Axis Title if required

7. Click Apply
8. In case you want to export the chart data from here:
   - Left-click on the chart
   - From the menu bar:
     - Click File
     - Click Save As
     - Export as csv-file

5.5.2.3. Abaqus

Standard

1. Choose Displacement (U) & Reaction Forces (RF) as field outputs for the step you want to have the plot
2. Run the analysis
3. Open the odb
4. Reaction force over time:
   a) Click Create XY Data
   b) Select Source ODB history output
   c) Click Continue
   d) Select all entries with beginning Reaction force: of the nodeset your are interested in
   e) Click Save as
   f) Assign name, here “RF”, & in Save Operation select \( \text{sum}(XY,XY,\ldots) \)
5. Displacement over time:
   a) Click Create XY Data
   b) Select Source ODB history output
   c) Click Continue
   d) Select all entries with beginning Spatial displacement \( U_i \): of the nodeset your are interested in
   e) Click Save as
   f) Assign name, here “U”, & in Save Operation select \( \text{avg}(XY,XY,\ldots) \)
6. Reaction force over displacement:
   a) Click Create XY Data
   b) Select Source Operate on XY data
   c) Click Continue
   d) From Operators select Combine
   e) In the equation, at first select “U”, than “RF”, the equation than should be \( \text{combine} \("U","F"\) \)
   f) Select Plot Expression

Explicit

1. Choose Displacement (U), Reaction Forces (RF) & Nodal forces (NFORC) as field outputs for the step you want to have the plot
2. Run the analysis
3. Open the odb
4. Reaction force & Displacement over time:
   a) Click Create XY Data
   b) Select Source ODB field output
   c) Click Continue
   d) XY Data from ODB Field Output dialog:
5. Pre- and postprocessing with ParaView

i. In the Variables tab, select Unique nodal in the Position combobox and all necessary entry checkboxes, here RF1 and U1

ii. In the Elements/Nodes tab, select the requested nodeset

e) Click Save

5. Sum forces:

a) Click Create XY Data
b) Select Source Operate on XY data
c) From Operators select sum
d) In the equation, select all “RF1” entries” and click Add to expression
e) Click Save as & assign name “RF”

6. Average displacements:

a) Click Create XY Data
b) Select Source Operate on XY data
c) From Operators select avg
d) In the equation, select all “U1” entries” and click Add to expression
e) Click Save as & assign name “U”

7. Reaction force over displacement:

a) Click Create XY Data
b) Select Source Operate on XY data
c) Click Continue
d) From Operators select Combine
e) In the equation, at first select “U”, than “RF”, the equation than should be combine ("U", "F")
f) Select Plot Expression

Save XY data

1. Open the odb
2. Create all results
3. In the menu bar, click Report
4. Click XY
5. Adjust the dialog preferences according to your needs
5.6. Measuring

5.6.1. Node/point position

Sometimes it is necessary to get the exact position of a single point or selection of points. The following steps give you these informations and are explained for a selection of points. For an individual point some steps can be omitted.

1. Import the model
2. Generate and extract the selection of interest according to section 5.3
3. Display the node/point numbers according to subsection 5.4.2
4. Remember the node/point numbers
5. In the RenderView select Split Horizontal
6. Create a new SpreadSheet View
7. In the SpreadSheet View:
   - Select your selection in the Showing combobox
   - Select Point Data in the Attribute combobox
   - The coordinates appear in the Points column of the table
   - In case not all your selected points appear in the table, check if the blocks the points are part of are selected in the Properties tab of your selection
8. Unfortunately the node/point number labels disappear

![Figure 5.6: Display of selection point/node positions](image-url)
5.6.2. Node/point distance

To measure the distance between two nodes or collocation points after importing the model:

1. In the menu bar
   - Click on Sources
   - Click Ruler
2. In the render view
   - Left-click the first point and keep the mouse clicked
   - Move the point close to the target
   - Press “CTRL+1” and snap the point to the closest mesh point
   - Do the same for the second point, but press “CTRL+2” instead for snapping
3. In the Ruler properties window
   - Adjust preferences to your need
   - Click Apply
4. The number next to the Ruler in the render view is the point distance
5. Pre- and postprocessing with ParaView

5.7. Exporting

5.7.1. Quick Screenshot

Screenshot are taken from the current view you see in ParaView render view. Therefore, perform all adjustments to the view to your needs before creating a screenshot.

To save a screenshot from ParaView perform the following steps:

1. Click **File** in the menubar
2. Click **Save Screenshot**
3. Set plot preferences:
   - Uncheck **Save only selected view** if necessary
   - Activate the **Lock aspect** button right of the resolution
   - Change the resolution to values high enough for a print-quality picture
     (the higher value should at least be 1000)
   - Select **image quality** slider 100
   - Override color palette: **Current palette**
   - Stereo Mode: **No stereo**
4. Click **Ok**
5. Specify the path and **File name**
6. Choose **PNG image** as file type
7. Click **Ok**

Afterwards, use **GIMP**, **Inkscape**, **convert** utility from **ImageMagick** or any other tool to convert the pixel to a non-scalable vector graphics copy as **eps** and **pdf** copy.

For the sake of reproducibility of the created picture save the ParaView state as described in section 5.7.4.

The target must be to have the figure and the ParaView state file available at all time:

<table>
<thead>
<tr>
<th>figure_name.ep</th>
</tr>
</thead>
<tbody>
<tr>
<td>figure_name.pdf</td>
</tr>
<tr>
<td>figure_name.png</td>
</tr>
<tr>
<td>figure_name.pvsm</td>
</tr>
</tbody>
</table>
5. Pre- and postprocessing with ParaView

5.7.2. Vector graphics - kind of

The vector graphics output only affects the non-3D rendered elements such as texts, cube axes etc. Normal or glyph plots which are 3D rendered are not affected. Therefore, this option is currently no use for the documentation. It is proposed to create high-quality png-plot with the Save Screenshot function and use GIMP, Inkscape, convert utility from ImageMagick or any other tool to convert the pixel to a non-scalable vector graphics copy.

5.7.3. Animations

ParaView allows the creation of animations for your currently selected view entity. So choose your plot coloring and vector entities before creating an animation.

To save an animation from ParaView perform the following steps:

1. Click File in the menubar
2. Click Save Animation
3. Set animation preferences:
   - Animation duration: 
   - Frame rate: ≥15
   - The human brain perceives successive images as moving, but not necessarily smooth, scene from about 14 to 16 frames per second.
   - No. of Frames/timestep: 1
   - Number of Frames: 
   - Resolution: higher value ≥ 1000
   - Timestep Range: Start- and end time step of interest
   - Stereo Mode: No Stereo
   - Compression: Checked
4. Click Save Animation
5. Specify the path and File name
6. Choose the file type of your liking, either video or multiple images
7. Click Ok

For the sake of reproducibility of the created animation save the ParaView state as described in section 5.7.4.

The target must be to have the animation and the ParaView state file available at all time:

animation_name.avi
animation_name.pvsm
5. Pre- and postprocessing with ParaView

5.7.4. Save ParaView states for exported items

For the sake of reproducibility of the created picture or animation you can save the ParaView state. If you want to reproduce the picture or animation you can just load the state and all preferences will be set to the exact values of the saved state.

To save a state perform the following steps:

1. Click File in the menubar
2. Click Save State
3. Specify the path of the figure or animation directory and the File name identical to the figure file name
4. Choose ParaView state file (*.pvsm) as file type
5. Click Ok

A state can be loaded accordingly:

1. Click File in the menubar
2. Click Load State
3. Select the state file
4. Click Ok
5.8. Preferences

5.8.1. Change mesh on sphere Glyph

Sometimes for nice publication pictures the default sphere glyph representation might be a little too angular. Internally, sphere glyphs are nothing but a combination of a certain number of tetrahedron elements. Thus, the mesh behind a sphere glyph might be too coarse. It is assumed you already have a glyph as spheres, otherwise have a look at subsection 5.4.4.

In order to change the mesh size and smooth the sphere shape perform the following steps:

1. Select the Glyph in the Pipeline Browser
2. In the Properties tab
   - Below the top line press the gear symbol 🔄
   - Additional options in section Glyph Source appear
   - Adjust the values for Theta resolution and Phi resolution to your needs. The default coarse value is 8.
   - Click 🔄 Apply

The result is compared in Figure 5.8. The mesh refinement has a significant impact on the computational performance. So only use the refined mesh if it is really necessary.

![Figure 5.8: Peridigm collocation points inside the base finite element mesh with different glyph resolutions](image)

(a) Resolution=8  (b) Resolution=24
5. Pre- and postprocessing with ParaView

5.9. Calculate

5.9.1. Cell center

1. Import your model and create a selection if only specific cell volumes are of interest.
2. Select the model or selection in the Pipeline Browser
3. From the menu bar:
   - Click Filters
   - Click Alphabetical
   - Click Cell centers
4. In the Properties tab
   - Select all blocks of interest in the Composite Data Set Index
5. Click Apply
6. Open a new Spreadsheet View
7. In the Showing combobox select your Cell Center Filter Name and Point Data in the Attribute combobox
8. Column points shows the cell center

5.9.2. Cell volume

A method is described that allows the calculation/extraction of the cell or element volume. This solution is copied from the Paraview Mailing List.

1. Import your model and create a selection if only specific cell volumes are of interest.
2. Select the model or selection in the Pipeline Browser
3. From the menu bar:
   - Click Filters
   - Click Data Analysis
   - Click Programmable Filter
4. In the Properties tab
   - Add to the Script field:
     ```python
     from vtk.numpy_interface import algorithms as algs
     volume = algs.volume(inputs[0])
     output.CellData.append(volume, 'volume')
     ```
   - Select all blocks of interest in the Composite Data Set Index
5. Pre- and postprocessing with ParaView

5. Click Apply
6. Open a new Spreadsheet View
7. In the Showing combobox select your Programmable Filter and Cell Data in the Attribute combobox
8. Column volume shows the cell volume

Figure 5.9.: Display of cell volume calculation
6. Benchmark results with *Peridigm*

*Peridigm* comes with several example problems as well as unit-test models which can be found in the following directories of the *Peridigm* installation folder.

- `/examples/`
- `/test/`

Further examples are available and documented in the *Peridigm* Models and Verification Guide which is part of the same repository.

Appendices
A. This document

A.1. Repository

This document is part of the PeriDoc repository. The complete repository can be found at:

https://github.com/PeriDoX/PeriDoX

A tool implementing the subversion protocols can be used to access the repository as well as update the files or commit changes using command line options or a graphical user interface.

Following is a list of tested possible tools:

<table>
<thead>
<tr>
<th>Operating system</th>
<th>Tool</th>
<th>Homepage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>TortoiseSVN</td>
<td><a href="https://tortoisesvn.net">https://tortoisesvn.net</a></td>
</tr>
<tr>
<td>Linux with KDE</td>
<td>KDESvn</td>
<td><a href="http://kdesvn.alwins-world.de/">http://kdesvn.alwins-world.de/</a></td>
</tr>
</tbody>
</table>

A.2. Typesetting

This document is originally typeset using the documentclass dlrreprt from the RM-LATEX package. For installation, see the Peridigm installation guide from this repository.

The compilation is performed with pdflatex with the following options:

```
pdflatex --shell-escape -synctex=1 -interaction=nonstopmode %source --extra-mem-top=60000000
```

The RM-LATEX package is not publicly available. Therefore, this document is compatible with a bootstrap-version of the documentclass, called bootstrap_dlrreprt. This class can be found in the same repository.
B. FAQ

B.1. Peridigm

When I call Peridigm with mpirun I get an error that the program is unable to find
the mesh file. What can I do?
  ➔ This problem occurs for CUBIT mesh files (*.g)
  ➔ Before using them in a parallel job you have to decompose the mesh according to
the number of processors to be used
  ➔ Please consult section 4.1.1.1

Everything works fine but when I call decomp I get a ***HDF5 library version
mismatched error*** error. Why?
  ➔ Check this same question in the Peridigm Installation Guide from this same repository.

I get the following error message combination: Throw test that evaluated to
ture: !boost::math::isfinite((*force)[i]) and **** NaN returned by force evaluation..
Why?
  ➔ It may be that your model became numerically unstable. Try to calculate the model
again with a decreased value for the solver timestep safety factor.

I get the following error message: ***** Error: getFieldId(), label not found:
Force when using a Compute Class Parameters. Why?
  ➔ Make sure you request the Variable as a normal Output Variable as well. Have a
look at the remarks in sections 3.8.1.3, 3.8.2.3 & 3.8.3.3.
  ➔ E.g. if your Compute Class Parameter is a force, Force must also be specified in
the output section

I get the following error message: Error! An attempt was made to access parameter
"ABC" of type "int" in the parameter (sub)list "ANONYMOUS" using the incorrect
type "double"! in when using the function parser for an input parameter. Why?
  ➔ Make sure that the equation for the function parser does not result in a numerical
value that can be expressed as an integer. E.g. With the values#{DISPLACEMENT=1.0}
and#{VELOCITY=1.0} the Final Time of a solver Final Time {DISPLACEMENT/VELOCITY}
supposedly is 1.0. However, for the function parser the result is 1 as an integer. As a
double value is expected for Final Time an error is thrown.
I get the following error message: Error, the parameter "ABC" is not a list, it is of type "double"! using the free format (.peridigm model). Why?

Make sure there are no tabs in the line of “ABS”. If there are, replace them with spaces and adjust the indentation of the line to the free format in your model.

Nothing happens when I use the Implicit solver and time-dependent Prescribed Displacements. Why?

This seems to be a bug in the calculation of the forces.

See https://github.com/peridigm/peridigm/issues/23
