# LIST OF FIGURES

2.1 Data structure for the SciGRID_gas data set .......................... 12

3.1 Screenshot of “Adobe Acrobat Reader” with the expanded layers tab, and a list of some layers to the left. 21

3.2 Screenshot of the “Transformation Settings” window. .................. 23

3.3 Screenshot of a sample location of the Russian-Polish border in the Gdansk Bay. ................................................. 23

3.4 Screenshot of the new window “Enter Map Coordinates”. ............... 24

3.5 Screenshot of the window “Enter Map Coordinates” with the populated X/Y values. 24

3.6 Screenshot of the “GCP table” entry with the new pair of coordinates, within the “Enter Map Coordinates” window. ......................... 24

3.7 Screenshot of both layers around Luxembourg, showing the mismatch of the transformation. ......................... 25

3.8 Sample shapefile, prior to clean up, where entire shapefile area is covered by one or several large polygons. ........................ 26

3.9 Sample shapefile, after the clean-up, where all polygons are pipelines. .................................................. 27

3.10 Sample shapefile, where a single polygon has been selected (yellow area with red stars) 27

3.11 Sample shapefile, after the removal of the above selected polygon. 27

3.12 Sample shapefile, with polygon between pipelines. .................... 28

3.13 Sample shapefile, with polygon selected between pipelines. ........ 28

3.14 Sample shapefile, with above selected polygon removed. ............. 28

3.15 Sample shapefile, with polygon between two parallel pipelines selected (yellow and red). 29

3.16 Sample shapefile, with polygon between two parallel pipelines removed. .......................................................... 29

3.17 Pipelines in Belgium prior to chunking and joining. ...................... 30

3.18 Pipelines in Belgium joined through the chunking and joining process. 30

3.19 The pipelines, storage facilities and production sites of the EMAP data set. ........................................... 35

3.20 SciGRID_gas data set for France. ........................................ 36

3.21 EntsoG PDF input data set for France. .................................. 36

5.1 SciGRID_gas (top) and EntsoG (bottom) pipelines for Spain and Portugal .................................................. 45

5.2 SciGRID_gas (top) and EntsoG (bottom) pipelines for France ........ 46

5.3 SciGRID_gas (top) and EntsoG (bottom) pipelines for Germany .... 47

5.4 SciGRID_gas (top) and EntsoG (bottom) pipelines for Belgium, Holland and Luxemburg 48

5.5 SciGRID_gas (top) and EntsoG (bottom) pipelines for Austria, Czech Republic and Slovakia 49

5.6 SciGRID_gas (top) and EntsoG (bottom) pipelines for Greece, Turkey and Bulgaria 50

5.7 SciGRID_gas (top) and EntsoG (bottom) pipelines for Italy ........... 51

5.8 SciGRID_gas (top) and EntsoG (bottom) pipelines for Ireland and UK 52

5.9 SciGRID_gas (top) and EntsoG (bottom) pipelines for Poland ........ 53

5.10 SciGRID_gas (top) and EntsoG (bottom) pipelines for the North Sea 54

5.11 SciGRID_gas (top) and EntsoG (bottom) pipelines for the Baltic Sea 55

5.12 SciGRID_gas (top) and EntsoG (bottom) pipelines for Ukrain 56

5.13 SciGRID_gas (top) and EntsoG (bottom) pipelines for Belarus 57

5.14 SciGRID_gas (top) and EntsoG (bottom) pipelines for Russia 58

Summary

The goal of SciGRID_gas is to develop methods to create an automated process that can generate a gas transmission network data set for Europe. Gas transmission networks are fundamental for simulations by the gas transmission modelling community, to derive major dynamic characteristics. Such simulations have a large scope of application, for example, they can be used to perform case scenarios, to model the gas consumption, to minimize leakages and to optimize overall gas distribution strategies. The focus of SciGRID_gas will be on the European transmission gas network, but the principal methods will also be applicable to other geographic regions.

Data required for such models are the gas facilities, such as compressor stations, LNG terminals, pipelines, etc. One needs to know their locations, in addition to a large range of attributes, such as pipeline diameter and capacity, compressor capacity, configuration, etc. Most of this data is not freely available. However throughout the SciGRID_gas project it was determined, that data can be found and grouped into two fundamental different groups: a) OSM data, and b) non-OSM data. The OSM data consists of geo-referenced facility data that is stored in the OpenStreetMap (OSM) data base, and is freely available. However, the OSM data set currently contains hardly any other information than the location of the facilities. The Non-OSM data set can fill some of those gaps, by supplying information such as pipeline diameter, compressor capacity and more. Part of the SciGRID_gas project is to mine and collate such data, and combine it with the OSM data set. In addition heuristic tools are required to fill data gaps, so that a complete gas network data set can be generated.

Here, this document describes one of the non-OSM data set, called the “EMAP” data set, which was generated from an EntsoG PDF map [EntsoG20]. This document here explains the origin and structure of this single data sets, and how the data set was generated.

In this document, the chapter “Introduction” will supply some background information on the SciGRID_gas project, followed by the chapter “Data structure”, that gives a detailed description of the data structure that is being used in the SciGRID_gas project. Chapter “Data sources” describes the EMAP data set.

The appendix contains a glossary, references, location name alterations convention and finishes with the table of country abbreviation.
SciGRID_gas is a three-year project funded by the German Federal Ministry for Economic Affairs and Energy [BMWi20] within the funding of the 6. Energieforschungsprogramm der Bundesregierung [BMWi11].

The goal of SciGRID_gas is to develop methods to generate and provide an open-source gas network data set and corresponding code. Gas transmission network data sets are fundamental for the simulations of the gas transmission within a network. Such simulations have a large scope of application, for example, they can be used to preform case scenarios, to model the gas consumption, to detect leaks and to optimize overall gas distribution strategies. The focus of SciGRID_gas will be the generation of a data set for the European Gas Transmission Network, but the principal methods will also be applicable to other geographic regions.

Both the resulting method code and the derived data will be published free of charge under appropriate open-source licenses in the course of the project. This transparent data policy shall also help new potential actors in gas transmission modelling, which currently do not possess reliable data of the European Gas Transmission Network. It is further planned to create an interface to [MMK16] or heat transmission networks. Simulations on coupled networks are of major importance to the realization of the German Energiewende. They will help to understand mutual influences between energy networks increase their general performance and minimize possible outages to name just a few applications.

This project was initiated, and is managed and conducted by DLR Institute for Networked Energy Systems.

1.1 Project information

- **Project title**: Open Source Reference Model of European Gas Transport Networks for Scientific Studies on Sector Coupling (*Offenes Referenzmodell europäischer Gastransportnetze für wissenschaftliche Untersuchungen zur Sektorkopplung)*
- **Acronym**: SciGRID_gas (Scientific GRID gas)
- **Funding period**: January 2018 - July 2021
- **Funding agency**: Federal Ministry for Economic Affairs and Energy (*Bundesministerium für Wirtschaft und Energie*), Germany
- **Funding code**: Funding Code: 03ET4063
- **Project partner**: DLR Institute for Networked Energy Systems
1.2 Background

As of today, only limited data of the facilities of the European Gas Transmission Networks is publicly available, even for non-commercial research and related purposes. The lack of such data renders attempts to verify, compare and validate high resolution energy system models difficult, if not impossible. The main reason for such sparse gas facility data is often the unwillingness of transmission system operators (TSOs) to release such commercially sensitive data. Regulations by EU and other lawmakers are forcing the TSOs to release some data. However, such data is sparse and too often not clearly understandable for non-commercial operators, such as scientists.

Hence, details of the gas transmission network facilities and their properties are currently only integrated in in-house gas transmission models which are not publicly available. Thus, assumptions, simplifications and the degree of abstraction involved in such models are unknown and often undocumented. However, for scientific research those data sets and assumptions are needed, and consequently the learning curve in the construction of public available network models is rather low. In addition, the commercially sensitivity also hampers any (scientific) discussion on the underlying modelling approaches, procedures and simulation optimization results. At the same time, the outputs of energy system models take an important role in the decision making process concerning future sustainable technologies and energy strategies. Recent examples of such strategies are the ones under debate and discussion for the Energiewende [BundesregierungDeutschland20] in Germany.

In this framework, the SciGRID_gas project initiated by the research centre DLR Institute of Networked Energy Systems in Oldenburg aims at building an open source model of the European Gas Transmission network. Releasing SciGRID_gas as open-source is an attempt to make reliable data on the gas transmission network available. Appropriate (open) licenses attached to gas transmission network data ensures that established models and their assumptions can be published, discussed and validated in a well-defined and self-consistent manner. In addition to the gas transmission network data, the Python software developed for building the model SciGRID_gas are published under the GPLv3 license.

The main purpose of the SciGRID_gas project is to provide freely available and well-documented data on the European gas transmission network. Further with the documentation, and the Python code, users should be able to generate the data on their own computers.

The input data itself is based on data available from openstreetmap.org (OSM) under the Open Database License (ODbl) as well as Non-OSM data gathered from different sources, such as Wikipedia pages, fact sheets from TSOs or even newspaper articles.

The main workload of this project is to:

- retrieve the OSM and Non-OSM data sets for the gas infrastructure
- merge all available data sets
• build a gas transmission component data set
• generate missing data using heuristic methods
• remove all gas facilities that are not connected to pipelines.
A well designed and documented data structure is fundamental in any large scale project. Good data structure in combination with tools, based on algorithms, improve the performance of any project output.

This structure needs to represent the gas flow facilities as good as possible. Hence, it needs to include components, such as pipelines, compressors, etc. A finite number of components have been identified, that are required as building blocks of a gas network. In addition each component will contain attributes, such as pipeline diameter, maximal operating pressure, maximal capacity, number of turbines etc.

It is anticipated, that the adopted data structure can be implemented in different types of gas flow models and will be used by the research community for topics, such as sector coupling or identifying gas transmission bottlenecks.

Within the SciGRID_gas project, the structure of the data model is part of classes defined within the Python code. Alterations may occur over the duration of the project, but it is envisaged, that those will be small, and that compatibility will be assured.

The goal of this section is to describe in details the data structure that has been adopted and implemented into the Python code. This will be important in understanding other aspects of this document, such as exporting the data into CSV files or generating missing values.

2.1 Data structure description

This section contains information on the SciGRID_gas data structure, the format, and the code that can be used to import publicly available data into the project, so that it can be used in subsequent steps. Paramount for an understanding of the data structure is a good understanding of the terminology used throughout this section and the document in general. Hence, terminology will be introduced in the following sub-section.

2.1.1 Terminology

Throughout this document certain terms will be used, which will be described below and have been summarized in Figure 2.1.
Figure 2.1: Data structure for the SciGRID_gas data set
Gas transmission network

The term “gas transmission network” describes the physical gas transmission grid. This does not include the distribution of gas through gas distribution companies, but includes the long distance transmission of gas from producer countries to consumer countries, as carried out by the Transmission System Operators (TSO) [Wik20g]. In addition, throughout this document, the terms “transportation” and “transmission” are seen as interchangeable, and hence, will both be used describing the same.

Gas component data set

The term “gas component data set” is used for all raw data of objects/facilities that have been loaded using SciGRID_gas tools into a Python environment. Gas component data sets are used as input into our SciGRID_gas project. Several data sources can be loaded as gas component data sets, and then combined into a single gas component data set. However, not all elements (e.g. compressors) must be connected to pipelines. Hence, such a data set is referred to as a “gas component data set”.

Gas network data set

A “gas component data set” can be converted into a “gas network data set”, by connecting all non-pipeline elements to nodes and all nodes are connected to pipelines, and as part of the process all network islands have been connected or removed, resulting in a single network. Therefore the network contains nodes and edges which are coherently connected, and all objects with the exception of pipelines are associated with nodes in this network, whereas pipelines are associated with edges.

Component

There are several component types in a gas transmission network, such as compressors, LNG terminals, or pipelines. In Figure 2.1 they are coloured red. Hence, whenever the word “component” is mentioned, it refers to one of these components. There are roughly a dozen different components that will form a gas network data set. They will be briefly explained below.

Element

The term “element” refers to individual facilities, e.g. the LNG terminal in Rotterdam, or the compressor in Radeland. In Figure 2.1 they are coloured blue. The first one is an element of the component LNG terminals, whereas the second one is an element of the component compressors. Hence, many elements make up a component. However, all elements are referring to different facilities by default. This means in a single network, one cannot have two elements of a component describing the same facility. The structure of elements is described below.

Attribute

“Attribute” is a term that is being used for the individual parameters that are associated with the elements. Examples of this term are gas “pipeline diameter”, “maximum capacity”, “max gas pipeline pressure”, to name just a few and in Figure 2.1 they are coloured yellow. Overall there will be several hundred attributes in the SciGRID_gas project. However, the same attributes can occur in more than one component, e.g. “max flow capacity” exist for pipelines and also for compressors. Throughout the project, we have tried to keep the units of such attributes the same, so that there is no unit conversion required.
Attribute value

Each attribute has a value, most likely a number or a string. In Figure 2.1 they are coloured black. While booleans (True/False) are also allowed, more likely a “1” will stand for True and “0” for False. However, not all attribute values are given. Therefore a no value attribute value needs to be specified. In the SciGRID_gas Python code it is None.

The Figure 2.1 depicts the relationships between the terms “gas data set”, “component”, “element”, “attribute”, and “attribute value”. As can be seen, a single gas data set consists of several components. On the next level, each component contains several elements. Further, each element has several attributes, where each attribute has a value. The heuristic processes described in this document at a later stage will fill all missing values with heuristically generated values.

Gas component types

A gas transmission network consists of different components, such as pipelines, compressors, etc. For the SciGRID_gas project a hand-full of components have been implemented, and will be described here briefly:

- **Nodes**: In a gas network, gas flows from one point to another point, which are given through their coordinates. All elements of all other components (such as compressor stations and power plants) have an associated node, which allows for the geo-referencing of each element. Overall the term Nodes will be used throughout this document, as it aligns with graph theory aspects.

- **PipeLines**: PipeLines allow for the transmission of the gas from one node to another. PipeLines are georeferenced by an ordered list of nodes.

- **PipeSegments**: PipeSegments are almost identical to PipeLines. However, are only allowed to connect two nodes. Hence, any PipeLines element can easily be converted into multiple PipeSegments elements.

- **Compressors**: Compressors represent compressor stations, which increases the pressure of the gas, and hence, allows the gas to flow from one node to another node. A gas compressor station contains several gas compressors units (turbines).

- **LNGs**: LNGs is the acronym for the LNG terminals and LNG storages, which there are several in Europe, as some gas gets transported to Europe via ships.

- **Storages**: Storages are a further network component. Surplus gas can be stored underground (e.g. in old gas fields or salt caverns), and used during low supply or high demand periods.

- **Consumers**: Consumers is the term used for gas users, which can be households, industry, power plants or others.

- **Production**: These can be wells inside a country where gas is pumped out of the ground. Most of the gas used in Europe comes from outside of the EU. However, there are several smaller gas production sites scattered through Europe.

- **BorderPoints**: BorderPoints are facilities at borders between countries, which are mainly used to meter the gas flow from one country to another.

- **EntryPoints**: These are special border points at the border of the European Union.

- **InterConnectionPoints**: These are connection points between gas transmission operators, and will be found mainly within Europe, in particular at country borders.
Element structure

As described above, elements are describing individual facilities, such as compressors or LNG terminals. However, the overall structure of those elements is the same for all elements of all components, and is described as follows:

- **id**: A string that is the ID of the element, and must be unique.
- **name**: A string that is the name of the facility, such as “Compressor Radeland”.
- **source_id**: A list of strings that are the data sources of the element. As several elements from different sources could have been combined into a single element, one might need to know the original data sources.
- **node_id**: The ID of a geo-referenced node to which an element of the network is associated to. For a compressor, this will be just a single node_id. However, for a gas pipeline this entry would be a list of at least two node_id values: the starts node id and the end node id.
- **lat**: The latitude value of an element. For elements of type PipeLines and PipeSegments lat is a list of latitude values. Throughout the SciGRID_gas project the projection World Geodetic system 1984 (epsg:4326) will be used.
- **long**: The longitude, analogue to lat.
- **country_code**: A string indicating the 2-digit ISO country code (Alpha-2 code, see Chapter 5.5 for list of countries and their codes) of the associated node of elements or list of nodes in case of PipeLines or PipeSegments.
- **comment**: An arbitrary comment that is associated with the element.
- **tags**: This dictionary is reserved for OpenStreetMap data. It contains all associated key:value-pairs of an OpenStreetMap item.

In addition, there are three further groups of attributes to each element, which have been coded as Python “dictionaries”, named:

- **param**
- **method**
- **uncertainty**

The structure within each dictionary is the same. The dictionary **param** (short for “parameter”) contains a list of attributes and their values. This list of attributes will be different for each component. For the component PipeLines they might be pipeline diameter, max pipeline pressure, and max pipeline capacity. For the component Compressors they might be, such as number of turbines, overall turbine power, energy source of turbine and more.

So the other two attribute dictionaries are **method** and **uncertainty**. Each of those two dictionaries contains exactly the same list of attributes as the **param** dictionary. However, their attribute values reflect the name of the dictionary. E.g. the attributes in the dictionary **method** contain the information on the method used to derive the attribute value that is stored in the **param** dictionary. Here methods of value generation can include heuristic methods names (in form of strings) that have been implemented in the SciGRID_gas project. However, if attribute values are not being generated by the SciGRID_gas project, but originate from one of the input data sources, then the attribute values in the **method** dictionary is set to “raw”.

See example below, for an LNGs element with the following entries: - “make_Attrib(const)”: the attributes end_year, and is_H_gas have been set to a constant value - “raw”, indicating that the two attributes max_cap_store2pipe_M_m3_per_d and start_year contain original values - “Lasso(max_cap_store2pipe_M_m3_per_d)”, here for the attribute median_cap_store2pipe_M_m3_per_d a method was used that is based on the lasso method and uses the attribute max_cap_store2pipe_M_m3_per_d as input.

Similar is the content of the **uncertainty** dictionary. It contains information on the uncertainty of the attributes from the **param** dictionary of that component. Again all attributes listed in the **param** dictionary are also present in the **uncertainty** dictionary. The attribute values here reflect the uncertainty of the attribute. Here, it is assumed, that
attributes with a method of “raw” have an uncertainty of zero. Only for those attributes, which were generated during heuristic SciGRID_gas methods an uncertainty larger than zero will be specified.

2.2 Summary

The SciGRID_gas software is designed to construct a gas transmission network data set form different open source gas component data sets. The gas transmission data set needs to be available and stored in a precise and predefined way, which was described in this section. We have identified several component-types of a gas transmission network grid, like pipelines, compressor stations, LNG-terminals, etc. Each specific facility that falls under such a component is considered an element of that component. Each element is described by a list of attributes and correspondent attribute values.
CHAPTER
THREE

DATA SOURCES

Original data sets describing gas transmission networks are the property of the transmission system operators (TSOs) and are generally not freely available in the form and depth that is required for modelling purposes. The major reason for the difficulty of obtaining such data is that most of the gas network infrastructure, namely pipelines, is buried underground. Thus a pipeline diameter is hard to estimate locally. In addition, almost all of the data is commercially sensitive.

Nevertheless, some data is made available by gas transmission network operators, through different channels. E.g. information on the size and number of compressors could be made public through a press release, as part of a refurbishment. An example is given below (https://www.maz-online.de/Lokales/Teltow-Flaeming/Newe-Verdichterstation-entsteht-in-Radeland):

“Die Eugal-Pipeline dient dazu, Gas aus der neuen Ostseepipeline Nord Stream 2 bis zur tschechischen Grenze zu leiten. 275 Kilometer von ihr verlaufen in Brandenburg. Grundsätzlich soll die neue Leitung parallel zur bestehenden Opal-Pipeline gebaut werden.”

In addition some information can be found on company web pages, (https://www.open-grid-europe.com/cps/rde/SID-752BB6B5-E0A975F2/oge-internet-preview/hs.xsl/NewsDetail.htm?rdeLocaleAttr=en&newsId=50190C3B-E14F-4685-9E64-E40EEAB57A28):

Open Grid Europe (OGE) is investing roughly EUR 150 million at its compressor station in Werne to improve the security and flexibility of energy supply for North Rhine-Westphalia and Germany. The upgrade of the station, which is one of the hubs of the pipeline network, will allow gas flows to be switched (reversed) from north to south and south to north. In addition, OGE is preparing the station for the upcoming transition from L- to H-gas. Through this fitness programme, the station’s transmission capacity will increase by about 500,000 to 6.5 million m³/h, which is equivalent to the annual consumption of more than 2,100 single-family homes. The project, which is due for completion at the end of 2018, is fully on track.”

However, there is a public drive to gather such data and subsequently make it available. The major platform through which this is occurring is the Open Street Map database [Hel18]. OSM is a geo-referenced database through which people can supply geo-referenced information on all man-made and natural structures, ranging from mountains to buildings. To achieve this, people throughout the world wander the globe and geo-reference everything that they can find. This also includes gas-pipeline markers, compressor stations or LNG terminals. However, the major problem remains that one cannot measure or estimate the diameter of the underground pipelines, or the number and size of the compressor turbines, as compressors are within buildings, which are fenced off. Hence, such information is hardly supplied to the OSM platform.

For the reasons mentioned above, the available data can be separated into two different groups:

- OSM data: Data can be found in the OSM data base. OSM data is well geo-referenced, but contains little meta-information (information on the facility attributes, such as pipeline diameter or pipeline capacity). OSM data is very helpful to obtain accurate routes of pipelines.

- Non-OSM data: Non-OSM data have in general lower geographical accuracy but contain a lot of meta-information. Unfortunately, such information is only known for a few facilities. One exception to this rule
are shapefiles from TSOs. They are rare, but well geo-referenced. However, the resolution of the meta information can vary from TSO to TSO.

The following section will introduce non-OSM data sets, and at a later stage, this will be followed by a section on the OSM data.

3.1 Non-OSM data

Non-OSM data includes data from internet research, TSO press releases, TSO transparency platform, TSO public data, national open-source gas network data sets\(^1\), etc.

Some of the TSO information had to be made available due to EU-regulations. Other information has been made public as part of a company’s self-presentation and advertisement. The information used by the SciGRID_gas project focuses on:

- the quality of the data
- the format of the data
- the level of representation of the data
- and the copyright restrictions on the data.

In addition, each data source is unique. Source specific tools need to be developed, so that all data sources can be made accessible for the SciGRID_gas project.

A significant portion of the project was spent on finding non-OSM data sets. Further data sources might be available, but unknown to the authors. If the authors are made aware of additional sources, the project will try to incorporate those, as this would only increase the depth of the data available and increase the applicability of the gas network data set and model.

Non-OSM data sources are very specific, addressing only certain aspects of the entire gas infrastructure. E.g. the GIE [GasIEurop20] data set supplies information on the daily gas flow in and out of gas storages in LNG terminals. However, they fall short on specifying the fundamental information of the actual physical location. Other data sets, such as the LKD [FMWP+17] data set is quite detailed in respect of pipelines, compressors and consumptions, however, only available for Germany.

Hence, the main task is to look closely at each data source, distil which data attribute values can be used, how it can be downloaded and incorporated into the SciGRID_gas model, and identify the copyright restrictions on the data source.

Due to copyright regulations, there are roughly two groups of data:

- Non copyright restrictive data (N-CRRD): here the copyright does not restrict the download, use and distribution of the data.
- Copyright restrictive data (CRRD): here the data can be downloaded and used internally, but not re-distributed to others.

The following is a list of the data sources that will be used throughout the project and an identification into which group of copyright restriction they fall:

- OSM (https://www.openstreetmap.org) (N-CRRD)
- ENTSOG (https://transparency.entsog.eu/) (CRRD)

\(^1\) An entire gas network data set is only available from the UK, see https://www.nationalgridgas.com/land-and-assets/network-route-maps\(^1\).
SciGRID_gas: The raw EMAP data set, Release 2.0

- **EMAP** (https://www.entsog.eu/sites/default/files/2020-01/ENTSOG_CAP_2019_A0_1189x841_FULL_401.pdf) (CRRD)
- **GIE** (https://www.gie.eu/) (N-CRRD)
- **IGU** (https://www.igu.org/) (CRRD)
- **GasLib** (http://gaslib.zib.de/) (N-CRRD)
- **INET** (see RefsInternetData) (N-CRRD).

Each data set and source comes with a different copyright regulation. The copyright can be rather non-restrictive (e.g. INET) or can be restrictive (IGU). It is attempted to use only freely available data, so that such data can be re-distributed. In more restrictive data cases (IGU, GB), it is not allowed to download the data and distribute it to others. However, it is allowed to let other potential users know of the location of such data and supply them with tools that allow them to carry out the same data download and subsequent incorporation of the data into a gas network data set.

**Note:**

In case that other users are aware of other data sources, that might be useful to this project, please get in touch and supply us with a brief description of the data and the location of such data, so that additional tools can be developed to incorporate the data in this project. Please use the following email address: developers.gas(at)scigrid.de
3.2 EntsoG-Map (EMAP) data set

This section contains information on the content and nature of the so called **EntsoG-Map (EMAP)** data set, how this data was generated, its format, and its content.

### 3.2.1 Origin of the data

The origin of the EMAP data is a map in PDF format supplied by EntsoG. EntsoG is the acronym for “European Network of Transmission System Operators for Gas”, and is an association of the European transmission system operators.

The EntsoG map covers all of Europe, including the non-EU states Russia, Ukraine, Belarus, Georgia, Azerbaijan, and others for the energy source gas. This map is being published on an irregular basis, and the latest version is from 2019. The project SciGRID_gas is very fortunate, that a map version of the gas pipelines, drilling platforms and storage facilities is available. As part of the project, tools have been created to incorporate some of the information from the map into the project.

The latest map version of EntsoG is available from the following link: [https://www.entsog.eu/sites/default/files/2020-01/ENTSOG_CAP_2019_A0_1189x841_FULL_401.pdf](https://www.entsog.eu/sites/default/files/2020-01/ENTSOG_CAP_2019_A0_1189x841_FULL_401.pdf)

The EntsoG map is freely available as a PDF file. Several steps need to be carried out to convert the PDF into the SciGRID_gas data structure. For this several Python tools have been created. However, this process cannot be fully automated. However, steps have been taken to automate as many aspects as possible, whereas some cleaning up will need to be carried out by hand by the user. The process of generating the data set is being described in more detail in Chapter 3.2.2, whereas the following section will inform the user of the data density of all important attributes.

### 3.2.2 EMAP generation processes

In this part of the chapter, a description is being given, on how the data set was generated, originating from a PDF document and resulting as a SciGRID_gas data object. Lustenberger et al. [LSS+19] presented a similar pathway of dissecting the same data set, however, using the non-open tool ArcGIS. Here, the open source tool QGis is being used. A comparison of those to data sets will be carried out at a later stage.

Below is a general overview of the steps that have been implemented to convert the EntsoG PDF map into a single SciGRID_gas gas network data set:

- Separate the individual layers from the original PDF map into separate files (**PDF Layer generation**).
- Convert the above PDF files into high resolution TIFF files (**PDF to TIFF conversion**).
- Geo-reference the TIFF file, which resulting in raster layers (**Geo-reference of TIFF files**).
- Convert the raster layers into SciGRID_gas PipeLines, Storages and Productions, for all of Europe (**Generation of SciGRID_gas network elements**).
- Remove little pipelines that are wrong artefacts of the PDF to TIFF conversion process (**Removing wrong elements**).
- Joining above data set into a single SciGRID_gas network data set, which will consist of many un-connected PipeLines, Storages and Productions (**Joining data**).
- Joining lose PipeLines, Storages and Productions to form one single SciGRID_gas network (**Generation of a single coherent SciGRID_gas data set**).

The overall outcome of this process is the conversion of the PDF map into more than 3000 PipeSegments elements, more than 200 Storages elements and more than 100 Productions elements throughout Europe, including Russia, and other non-EU states, resulting in a total length of more than 200000 km of pipe-lines.
The steps of how to convert the PDF map into the SciGRID_gas data are presented below.

**PDF Layer generation**

The data source is a PDF map of the European gas transmission network, including sites of *Productions*, *Storages*, under-sea *PipeLines* and overland *PipeLines* in different thicknesses, based on their throughput. This map can be downloaded from the EntsoG web page (see link above). As the PDF document consisted of several layers, one can use an external tool to separate those layers and remove unwanted layers, such as legend, coastal lines, or gas fields. This process needs to be done by hand in an application, such as “Adobe Acrobat Reader”. In this application, the layers tool can be selected, and individual layers can be saved as individual PDF layers. Below (see Figure 3.1) a screen shot shows the “Adobe Acrobat Reader” software with the EntsoG map loaded, and the layers tab expanded. Several layers can be seen in the screenshot and are part of the EntsoG map, such as “CAPDATA”, “datapanel GRAY”, “>>>>LEGEND” etc.

![Screenshot of “Adobe Acrobat Reader” with the expanded layers tab, and a list of some layers to the left.](image)

Most of the layers that are present in the EntsoG map do not contain information that are needed for this project, and can be discarded. But the following layers are required for the SciGRID_gas project:

- “>>, STORAGE NONEU”, will be part of the SciGRID_gas “Storages” component
- “>>, STORAGE TYNDP”, will be part of the SciGRID_gas “Storages” component
- “== DRILLPLATFORMS ==”, will be part of the SciGRID_gas “Productions” component
- “PIPELINES_NEW_GERMANY”, will be part of the SciGRID_gas “PipeLines” component
- “PEPELINES > SMALL”, will be part of the SciGRID_gas “PipeLines” component
- “PEPELINES > MEDIUM”, will be part of the SciGRID_gas “PipeLines” component
- “PEPELINES > LARGE”, will be part of the SciGRID_gas “PipeLines” component
- “=== NORTHSEA - pipes > GAS”, will be part of the SciGRID_gas “PipeLines” component

These layers need to be exported individually into single PDF files.

In addition, further layers are needed for the geo-referencing process at a later stage:

- “BORDERS”
- “SHORES”
- “LANDM Ass”.

These three layers need to be exported combined into a single PDF file, which will be referred to as the “ENTSOG_Borders” layer.
All resulting data files need to be stored in the following folder:
“../SciGRID_gas/Eingabe/Maps/EntsoG_2019/01_PDF/”

PDF to TIFF conversion

For later processes, the PDF files need to be converted into TIFF format. For this an external application, such as https://onlineconvertfree.com/de/convert-format/pdf-to-tiff/, can be used. The user should select an application, which retains as much resolution as possible.

Resulting TIFF files need to be stored in the following folder:
“../SciGRID_gas/Eingabe/Maps/EntsoG_2019/02_TIFF/”

Geo-reference of TIFF files

As the projection of the original map is unknown, we need to determine the projection using an external application, such as QGIS. For this one needs to load the layer ENTSOG_Borders which was generated in a previous step above. The overall plan is to geo-reference this layer ENTSOG_Borders and in a second step apply the determined georeferencing to all the actual gas facilities layers.

Hence, one needs to load the layer ENTSOG_Borders into QGIS, which is not geo-referenced at this stage. In addition, one needs to load a geo-referenced layer of Europe reference map or of the area of interest as well. Care needs to be taken, that the reference map is projected in the projection that has been selected for the SciGRID_gas project. In the case for Europe, the projection “epsg:4326” was selected.

Now the following QGIS process is required: “Georeference GDAL”. This is a plugin, that can be installed from within QGIS, for QGIS versions of smaller than 3. For version 3.0 and newer, this plugin comes pre-installed with the base installation. (If you have problems finding “Georeference GDAL” in QGIS 3.x, then follow instructions under link https://gis.stackexchange.com/questions/274503/georeferencing-in-qgis-3-0).

The tool “Georeference GDAL” can be found under “Raster” and then “Georeferencer . . . ”.

Here for SciGRID_gas the following steps need to be taken:

- Open QGIS.
- Open a reference map of the European country layers, here the user can use the “TM_WORLD_BORDERS-0.3” layer [San19], that can be downloaded from the following site: https://koordinates.com/layer/7354-tm-world-borders-03/.
- Start the Georeferencer, and new Georeferencer window will open.
- Press the [Open Raster] icon, and select the layer ENTSOG_Borders.
- Open the “Transformation Settings” window by pressing the [Transformation Settings] icon, and select the following as depicted in Figure 3.2:

Here, the user needs to select the following:

- “Transformation type”: “Thin Plate Spline”
- “Resemble method”: “Cubic Spline”
- “Target SRS”: “EPSG:4326 - WGS 84”

and press the [OK] button to finish off this setup.

- In the “Coordinate Reference System Selector” select the “epsg:4326” coordinate reference system.
- Select the [Add Point] icon.
• By pressing the [Shift] button and using the mouse wheel, the user can find striking features on the TIFF map and select the location by pressing the left mouse button on top of it. Here as an example (see Figure 3.3) the border between Russia and Poland is being displayed, and a good location would be where the border meets the Baltic Sea.

Figure 3.3: Screenshot of a sample location of the Russian-Polish border in the Gdansk Bay.

• After pressing the left mouse button, the following window will appear (see Figure 3.4):

• Find on the loaded georeferenced map (TM_WORLD_BORDERS) the appropriate location and press the left mouse button again. This will populate the X/Y coordinates in the “Enter Map Coordinates” window, as shown in Figure 3.5.

Press the return button to lock in this geo-referenced pair of values. - In the “Georeferencer” window an entry should appear in the “GCP table”, where the table is located below the map (Figure 3.6).

• Repeat this process for a large number of points throughout Europe. Select points on the peripheries of Europe, but also select points within Europe, e.g. the three border location of Belgium, Germany and the Nederland, or other territorial and geographical features, such as Isle of Guernsey or Isles of Scilly AONB. However, try not to
Figure 3.4: Screenshot of the new window “Enter Map Coordinates”. Here the user needs to press the [From map canvas] button.

Figure 3.5: Screenshot of the window “Enter Map Coordinates” with the populated X/Y values.

Figure 3.6: Screenshot of the “GCP table” entry with the new pair of coordinates, within the “Enter Map Coordinates” window.
use too many point pairs, a good spread is more important. (Here about 200 points were selected in the original process.)

- Now the user can check the geo-referencing by pressing the [Start Georeferencing] icon. This process might take several minutes. It will result in a new layer in the QGIS Layers list. Try to visualize this new layer and the “TM_WORLD_BORDERS-0.3”, by setting one layer slightly transparent, so that one can eye up the newly projected layer “ENTSOG_Borders” with the “TM_WORLD_BORDERS-0.3” layer and look for areas of large difference (example given in Figure 3.7). Now more pair points can be added to rectify areas of imperfect geo-transformation, until the user is satisfied with the result. As an example, Luxembourg is presented here, and one can see that the locations of the border triangle of Luxembourg, the Netherlands and Germany on the north and Luxembourg, the Netherlands and Belgium on the west are not perfect. Hence, placing additional geo-referencing pairs might help to rectify this discrepancy.

Figure 3.7: Screenshot of both layers around Luxembourg, showing the mismatch of the transformation.

- If the user is satisfied with the geo-referencing and the underlying pairs of values, the user needs to save the point pairs, as they will be used for the other TIFF layers. This can be achieved by pressing the [Save GCP Points as] icon in the “Georeferencer - . . .” window. A window will pop up and the user will need to enter a location and a file name of the points table.

Now the user needs to apply this same geo-referencing to the other layers of the EntsoG map. For this carry out the following steps:

- Select a new TIFF file from the layer list above in the “Georeferencer - . . .”.
- Open the previously saved GCP table by pressing the [Load GCP Points] icon.
- Select a different destination file under the [Transformation Settings] window.
- Initiate the geo-referencing process by pressing the [Start Georeferencing] icon.

This should be carried out for the PipeLines, Storages and Productions layers.

The overall output will be that the user will have created raster TIFF layers of the EntsoG gas elements, such as PipeLines, Storages and Productions, which are geo-referenced. Those resulting files should be stored in the folder: “../SciGRID_gas/Eingabe/Maps/EntsoG_2019/03_Raster/”.
SciGRID_gas: The raw EMAP data set, Release 2.0

Generation of SciGRID_gas network elements

In the next step, the user needs to convert the raster layer into SciGRID_gas elements. For this Python code can be executed by the user.

The Python routines are combined in the M_Maps module, and can be access with the M_Maps.read() function. A large list of settings are required. However, they have been implemented into the code as default values, if no other values are supplied.

The previous steps created a geo-reference raster layer. However, this raster layer needs to be converted into polygons, which subsequently need to be converted into SciGRID_gas PipeLines, Storages and Productions.

The functions that have been developed to carry out those transformations are listed below for each sub-section.

Raster to polygons

The main function that is being used to convert the raster files into polygons is called M_Maps.raster2Polygon(). This function uses the freely available GDAL Python module that can be downloaded and installed for Python. The resulting file format is of type shapefile, and resulting files will be stored in the folder “../SciGRID_gas/Eingabe/Maps/EntsoG_2019/04_Polygon/”.

The above process created a very large number of polygons, where some of the polygons are of the size of the PDF raster scanning resolution. To reduce the number of polygons, horizontally adjacent polygons are combined into single polygons, reducing the number of polygons by about 25%. Results of this process are written as shapefiles into the folder “../SciGRID_gas/Eingabe/Maps/EntsoG_2019/05_Polygon/”.

Manual shapefile clean up processes

After the above step the user needs to carry out a manual process. This is required, as the polygons created contain spatial “mistakes”, as polylines are surrounded by a polygons, as can be seen in Figure 3.8.

![Figure 3.8: Sample shapefile, prior to clean up, where entire shapefile area is covered by one or several large polygons.](image)

The goal is to remove all those polygons that are not lines, as is the case in Figure 3.9.

This can be achieved by using an application, such as QGIS, and selecting and removing the unwanted polygons. Figure 3.10 shows the entire shapefile, where a single polygon has been selected (yellow) which has been removed in the next process step, resulting in Figure 3.11.

As can be seen in Figure 3.12, even areas between pipelines can be polygons (grey area between pipelines). These need to be removed as well, and have been selected as shown in Figure 3.13, and results of the removal process can be found in Figure 3.14.
Figure 3.9: Sample shapefile, after the clean-up, where all polygons are pipelines.

Figure 3.10: Sample shapefile, where a single polygon has been selected (yellow area with red stars)

Figure 3.11: Sample shapefile, after the removal of the above selected polygon.
Figure 3.12: Sample shapefile, with polygon between pipelines.

Figure 3.13: Sample shapefile, with polygon selected between pipelines.

Figure 3.14: Sample shapefile, with above selected polygon removed.
However, there are polygons between parallel lines of pipelines that need to be removed as well. Such a polygon between two parallel lines can be seen in Figure 3.15, which has been selected already (red). After the removal process (Figure 3.16) the two parallel lines are better visible and will make it easier for subsequent processes to carry out the conversion process from polygons to SciGRID_gas elements.

![Figure 3.15: Sample shapefile, with polygon between two parallel pipelines selected (yellow and red).](image1)

![Figure 3.16: Sample shapefile, with polygon between two parallel pipelines removed.](image2)

Resulting number of polygons per component group were large, but not large enough for the UNIX computer used. Resulting files are written into the folder “../SciGRID_gas/Eingabe/Maps/EntsoG_2019/06_Polygon/One/”.

**Polygons to SciGRID_gas elements**

The main function that is being used to convert the polygons files into SciGRID_gas elements is called `M_Maps.polygons2Netz()`. This function calls several functions from other modules, e.g. `GDP.GeoSerie`, or creates instances from other class definitions, e.g. `geometry.Centerline()`. For this processes to work, component specific parameters had to be determined, and will be part of the default settings. The outputs of this process for all of Europe generated a specific SciGRID_gas component data sets.

Resulting data is being written into the folder “../SciGRID_gas/Eingabe/Maps/EntsoG_2019/07_A_CSV/One/”.

Here the resulting pipeline data sets received an attribute called `pipe_class_EMap` (see above).

Besides pipeline length, which will be generated dynamically at a later stage, this is the only attribute that was able to be extracted from the PDF map.
Removing wrong elements

During the digitization process and the subsequent processes of converting the data into a SciGRID_gas data set, wrong lines started to appear in the data sets. These need to be removed, as otherwise, they would be leading to wrong PipeLines elements, Productions sites, or Storages facilities. Hence, a function was written that removes pipe-lines, that are connected at only one end, and is called M_Maps.multi_removeStichPipeLines(). It was found that for some component elements, e.g. of type PipeLines, this function needed to be executed several times with varying settings, whereas it was not applied to any element of type Productions.

Resulting data is being written into the folder “./SciGRID_gas/Eingabe/Maps/EntsoG_2019/07_B_CSV/One/”.

A further function was designed that removes PipeLines elements, that are not connected at all. These are so called lone pipe-lines and can be removed by the function M_Maps.removeLonePipeLines(). Here any lone pipeline shorter than 2.55 km were removed.

Resulting data is being written into the folder “./SciGRID_gas/Eingabe/Maps/EntsoG_2019/07_C_CSVs/One/”.

Joining PipeSegments

At this part of the program, pipelines are being connected. However, this is being carried out for each group of pipelines, e.g. “PEPELINES > MEDIUM”, or “PEPELINES > LARGE”.

First of all, pipes were joined, if their end nodes were closer than a user defined distance. In a second step, all pipelines were broken up into smaller chunks (“chunking”), resulting in an increase of start and end nodes. Then it was investigated, if pipe ends were closer than a user specified value again. In this case, new pipes were added connecting those nodes. In a subsequent step, the pipes were de-chunked again where possible. An example is given in

The function carrying out this process is called M_Maps.ExtraJoin(), and resulting data is being written into the folder “./SciGRID_gas/Eingabe/Maps/EntsoG_2019/09_RawData/”.

![Figure 3.17: Pipeines in Belgium prior to chunking and joining.](image1)

![Figure 3.18: Pipeines in Belgium joined through the chunking and joining process.](image2)
Generation of a single SciGRID_gas data set

In this subsequent step, the different types of PipeSegments elements ("PEPELINES > MEDIUM", "PEPELINES > LARGE" etc.) are combined into a single SciGRID_gas data set. For this additional Python code needed to be executed to create additional connections, e.g. land based pipelines and off-shore drilling platforms.

Hence, the function M_Maps.joinDataSets() joins all the separate data sets into a single SciGRID_gas data set. Resulting data is being written into the folder "./SciGRID_gas/Eingabe/Maps/EntsoG_2019/10_Final/". The method applied is similar to the one described under "Joining PipeSegments", however pipes were only allowed to be connected, if they were not of the same type, e.g. a "PEPELINES > MEDIUM" pipe was not connected with another "PEPELINES > MEDIUM" pipeline, but could be connected with a pipe of the group "PEPELINES > LARGE".

Resulting data is being written into the folder "./SciGRID_gas/Eingabe/Maps/EntsoG_2019/10_Final/".

As it was noticed, that some vital pipelines were missing, an option has been implemented, that additional connections can be made. Information for the additional pipes is stored in a file called "../SciGRID_gas/Eingabe/Maps/EntsoG_2019/AdditionalPipeSegments.csv". It consists of a single header line, and the following five columns:

• long_1: Start longitude value of pipeline
• lat_1: Start latitude value of pipeline
• long_2: End longitude value of pipeline
• lat_2: End latitude value of pipeline
• Emap_Class: EMAP class value of pipeline

Here the user can add as many pipelines as required. For the current data set the pipes added are given in Table 3.1:

<table>
<thead>
<tr>
<th>long_1</th>
<th>lat_1</th>
<th>long_2</th>
<th>lat_2</th>
<th>Emap_Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1.9956</td>
<td>47.406</td>
<td>-2.45388</td>
<td>47.6069</td>
<td>2</td>
</tr>
<tr>
<td>9.5211</td>
<td>50.691</td>
<td>9.6987</td>
<td>50.7447</td>
<td>2</td>
</tr>
<tr>
<td>13.5415</td>
<td>50.6373</td>
<td>13.7921</td>
<td>50.5032</td>
<td>1</td>

<td>57.6529</td>
<td>2</td>
</tr>
</tbody>
</table>

Last cosmetic alterations to single SciGRID_gas data set

The final function M_Maps.finalTouch() modifies the single SciGRID_gas data set, by carrying out the following actions:

• setting the country code according to the lat/long values
• setting elevation values according to the lat/long values

Resulting data is being written into the folder "./SciGRID_gas/Eingabe/Maps/EntsoG_2019/15_Final/".

3.2. EntsoG-Map (EMAP) data set
3.2.3 EMAP data density

For each component the data density for the most relevant attributes will be given next.

**PipeSegments elements**

Overall, there are 7317 PipeSegments elements in the resulting EMAP data set. Table 3.2 summarizes the data densities for the most important PipeSegments attributes:

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Data density [%]</th>
</tr>
</thead>
<tbody>
<tr>
<td>length_km</td>
<td>100</td>
</tr>
<tr>
<td>pipe_class_EMap</td>
<td>53</td>
</tr>
<tr>
<td>exact</td>
<td>100</td>
</tr>
</tbody>
</table>

As each element of the component PipeSegments originated from a line in the original PDF map, and as this map was geo-referenced, a length for each element could easily be determined, therefore the overall data density for the attribute length_km is 100 %. In addition, for the attribute exact a blanket value of 3 has been assumed, indicating that the topological accuracy would be better than 100 km.

The attribute pipe_class_EMap is a value that was generated during the data generation process. The original PDF file contained three different layers for three different pipeline thicknesses: “small”, “medium”, and “large”. This was given for all pipelines in Europe, except for the regions of Germany and the North Sea. To be able to use that information of the “small”, “medium” and “large” attribute during the heuristic processes, these attributes were converted into an integer number as given in Table 3.3. The German pipeline layer contained all pipelines, from small to large. Hence, an overall value of two was assumed. For the pipelines in the North Sea a mixture of small, medium and large pipelines was given. However, one can assume that due to the transport from production sites to country border points, the pipelines would be larger on average. Hence, a value of 1.5 has been assumed for all pipelines in the North Sea.

<table>
<thead>
<tr>
<th>Type of pipe Segment</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>small</td>
<td>3</td>
</tr>
<tr>
<td>medium</td>
<td>2</td>
</tr>
<tr>
<td>large</td>
<td>1</td>
</tr>
<tr>
<td>Germany</td>
<td>2</td>
</tr>
<tr>
<td>North Sea</td>
<td>1.5</td>
</tr>
</tbody>
</table>

**Storages elements**

Overall, there are 177 Storages elements in the resulting EMAP data set.

The extraction process was not able to retrieve any further information for the Storages, except their locations.
**Productions elements**

Overall, there are 103 *Productions* sites in the resulting EMAP data set.

Again, the extraction process was not able to retrieve any further information for the *Productions*, except their locations.

**Nodes elements**

Overall, there are 6047 *Nodes* elements in the resulting EMAP data set.

Table 3.4 summarizes the data densities for the most important *Nodes* attributes:

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Data density [%]</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>exact</em></td>
<td>100</td>
</tr>
<tr>
<td><em>elevation_m</em></td>
<td>100</td>
</tr>
</tbody>
</table>

Here again, the information that has been used to generate a value for the attribute *exact* is the same as applied for the *PipeSegments*. Hence, each *Nodes* element was assigned a value of three.

The elevation attribute *elevation_m* was not retrieved from the EntsoG PDF map, but was generated using the APIs from Open Topo Data [Nis20] or Bing [Mic20].

**3.2.4 Changes to previous releases**

Changes in the code were implemented when compared with Version 1. The code here followed a different pathway of generating and joining the individual data sets. The major difference here is, that the problem of the pipes crossing borders has been eliminated.

**3.2.5 Copyright**

**Copyright**

Based on the legal framework, all of the EMAP was generated in such a way, that it has a copyright that does not restrict us from making the data available to other users.

Hence, the following applies to the EMAP data:

Open Access: The EMAP data set are licensed under a Creative Commons Attribution 4.0 International License, which permits the user to share, adapt, distribute and reproduce in any medium or format, as long as the user gives appropriate credit to the original author(s) and the source, provide a link to the Creative Commons license, and indicate if changes were made. The images or other third party material in this article are included in the article’s Creative Commons license, unless indicated otherwise in a credit line to the material. If material is not included in the article’s Creative Commons license and your intended use is not permitted by statutory regulation or exceeds the permitted use, you will need to obtain permission directly from the copyright holder. To view a copy of this license, visit [http://creativecommons.org/licenses/by/4.0/](http://creativecommons.org/licenses/by/4.0/)
Disclaimer

The EMAP data set is supplied on a best-effort basis only. While every effort is made to make sure the information is accurate and up-to-date, we do not accept any liability for any direct, indirect, or consequential loss or damage of any nature—however caused—which may be sustained as a result of reliance upon such information.

3.2.6 Summary EMAP Data

A PDF map of the European gas transmission network was available from through the “EntsoG” transparency platform. Tools have been created to convert the PDF into the SciGRID_gas data structure and make the data accessible throughout the SciGRID_gas project.

As can be seen, the geo-referencing did not optimal for countries on the African continent. However, as the dataset that is required focuses on Europe, those pipelines will not be part of the final SciGRID_gas data set. Having said this, their location is within the certainty of 100 km given (exact = 3).

The Table 3.5 summarises the number of elements for each component found:

<table>
<thead>
<tr>
<th>Component Name</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>BorderPoints</td>
<td>0</td>
</tr>
<tr>
<td>Compressors</td>
<td>0</td>

<tr>
<td>Nodes</td>
<td>6047</td>
</tr>
<tr>
<td>PipeSegments</td>
<td>7317</td>
</tr>
<tr>
<td>Production</td>
<td>103</td>
</tr>
<tr>
<td>Storages</td>
<td>177</td>
</tr>
</tbody>
</table>

Below the current version of the EMAP data set, is presented for all of Europe in Figure 3.19, resulting in a total of 223400 km of PipeSegments elements. However, it will need to be pointed out, that a large fraction of those pipes are in countries, which are outside of the scope of this project. In addition it will need to be pointed out, that this process described here was not that good in determining parallel pipelines.
Figure 3.19: The pipelines, storage facilities and production sites of the EMAP data set.
3.3 Visual Comparison of SciGRID_gas dataset and PDF input source

In addition the user can find pairs of plots of the plotted SciGRID_gas data set and the PDF input source for several countries in Chapter 5.6.

An example is been given here for France. The user can see the difference in the original input pipelines, and the generated SciGRID_gas pipelines. For most countries, the overlap is fairly good.

Figure 3.20: SciGRID_gas data set for France.

Figure 3.21: EntsoG PDF input data set for France.
3.4 Data summary

SciGRID_gas is based on open source data. To generate a gas pipeline network data set, one needs to access different data sets that were found throughout the project and presented here. Emphasis was given to depict the number of elements per component and the data density for each data set.

3.5 Summary

Gas component data sets come in different forms, licenses, formats and detail. The SciGRID_gas project can process such data and combine them to a consistent and reliable network data set.

The underlying gas component data sets were categorized into two different groups:

- OSM data: This is data originating from the OSM data base, containing well geo-referenced locations of gas facilities, such as pipe locations or gas storage facilities. However, it comes with very few meta information.

- Non-OSM data: These are all other data sources, which can “supply” detailed information on some of the gas facilities attributes. However, this information is sparse, as published only for a few facilities. Here, the INET data set was introduced as an example of the non-OSM data set, and the pathway of converting the raw data from the www into SciGRID_gas project component structure.

Here detailed information on one or several data sources have been given, and should be used as a reference for later data processes.
CHAPTER

FOUR

CONCLUSION

This document here is the documentation of one of the data sets that is part of the SciGRID_gas project. This document here started off with the introduction of the SciGRID_gas project, such as funding, duration and goals. In a subsequent chapter the data structure within the SciGRID_gas project was described, such as components, elements, attributes and attribute values, so that the transmission data set could be an input to certain gas flow model. The third chapter introduced the EMAP data set, which is a data set that was generated by dissecting a PDF map of the european gas network that is made available from EntsoG. The data presented here is the raw data with some missing values.

This resulted in data set, containing 178 storage locations, 103 production sites, and 7017 pipe segments resulting in 231,010 km of gas pipelines through Europe. Such a data set could be used for static gas flow models, and it is hoped that this data set will be used by the modelling community for answering some of the questions that could arise as part of the Energiewende, and other real world problems.
5.1 Glossary

Dataset abbreviations can be found in Table 5.1.

</tbody>
</table>

The glossary terms can be found in Table 5.2.
### Table 5.2: Glossary

<table>
<thead>
<tr>
<th>Name</th>
<th>Abbreviation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>component</td>
<td></td>
<td>A gas network consists of different components, such as: pipelines, compressors, LNG terminals, storages, entry points and production sites</td>
</tr>
<tr>
<td>element</td>
<td></td>
<td>Elements are instances of component. Hence, “10 compressor elements” refers to a data set that contains information for 10 compressor stations</td>
</tr>
<tr>
<td>attribute</td>
<td></td>
<td>Gas facilities, such as pipelines or compressors, can be described with a large set of parameters, such as pipeline diameter, or compressor capacity. Those parameters are referred to as attributes</td>
</tr>
<tr>
<td>facility</td>
<td></td>
<td>General term used for a gas appliance, such as a single compressor station, or a single LNG terminal</td>
</tr>
<tr>
<td>PipeLine</td>
<td></td>
<td>A gas pipeline entity, which has one start and one end point, however, can run via many nodes</td>
</tr>
<tr>
<td>PipeSegment</td>
<td></td>
<td>A gas pipeline, that has only one start and one end point, but no nodes in-between</td>
</tr>
<tr>
<td>LNG</td>
<td>LNG</td>
<td>Liquefied natural gas</td>
</tr>
<tr>
<td>CNG</td>
<td>CNG</td>
<td>Compressed natural gas</td>
</tr>
<tr>
<td>flow duration curve</td>
<td>FDC</td>
<td>It is the cumulative frequency curve that shows the percent of time specified flow were equal or exceeded during a given period. The temporal information, when certain events occur, is lost</td>
</tr>
<tr>
<td>Energiewende</td>
<td></td>
<td>German term for the change in using primary energies, the move away from coal to renewable energies, such as wind or solar</td>
</tr>
<tr>
<td>gas component data set</td>
<td></td>
<td>Raw input data, associated with components of the gas transmission grid</td>
</tr>
<tr>
<td>gas network data set</td>
<td></td>
<td>Output data, a coherent network of gas transmission components</td>
</tr>
<tr>
<td>OSM</td>
<td>OSM</td>
<td>Data that is available from the openstreetmap.org</td>
</tr>
<tr>
<td>non-OSM</td>
<td>Non-OSM</td>
<td>Data that is not part of the OSM data set</td>
</tr>
<tr>
<td>gas type</td>
<td></td>
<td>There are two types of gas High (H) and Low (L) calorific gas</td>
</tr>
<tr>
<td>mean absolute error</td>
<td>MAE</td>
<td>mean difference between input values and estimated values</td>
</tr>
<tr>
<td>data density</td>
<td></td>
<td>The ratio of the number of usable (not missing) attribute values over number elements of the component, in units of [%]</td>
</tr>
<tr>
<td>Transmission System Operators</td>
<td>TSO</td>
<td>An entity entrusted with the transportation of natural gas/electricity, as defined by the European Union</td>
</tr>
<tr>
<td>gas transmission network</td>
<td></td>
<td>This describes the physical gas transmission grid, however, it excludes any facilities/components that would be part of a distribution network and their facilities</td>
</tr>
<tr>
<td>gas component data set</td>
<td></td>
<td>The term “gas component data set” is used for raw data sets of gas network facilities. However, not all elements (e.g. compressors) need to be connected to pipelines, where the emphasis is on the term component</td>
</tr>
<tr>
<td>gas network data set</td>
<td></td>
<td>A “gas component data set” can be converted into a “gas network data set”, by connecting all non-pipeline elements to nodes and all nodes are connected to pipelines. Hence, the emphasis here is on the term network</td>
</tr>
</tbody>
</table>
5.2 Unit conversions

<td>gas Mm$^3$d$^{-1}$</td>
<td>24/1000</td>
</tr>
<tr>
<td>LNG Mm$^4$</td>
<td>gas Mm$^3$</td>
<td>584</td>
</tr>
<tr>
<td>LNG t</td>
<td>gas Mm$^3$</td>
<td>1442.48</td>
</tr>
</tbody>
</table>

5.3 Attribute exact

Each element of type Nodes has an attribute exact. With this, the SciGRID_gas project is trying to let the user know, how well the actual location of the Nodes elements are known. The actual location (latitude longitude pair) can be spot on (verifiable through satellite imagery) or can be unknown by 10’s or 100’s of km, where city names or country names are known only. Here the attribute value for exact is being given, ranging from “1” to “5” as listed in Table 5.4 below.

Table 5.4: Unit conversions

<table>
<thead>
<tr>
<th>Exact value</th>
<th>Description</th>
<th>Uncertainty [km]</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The exact location of this node is known, as one was able to verify the facility through satellite data.</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>Here the lat/long is not known exactly. However, one assumes that the location is within a small region (e.g. Krummhörn). Hence, not being much larger than 10 km</td>
<td>10</td>
</tr>
<tr>
<td>3</td>
<td>Here so little is known about the exact location, and one only knows, that the location is within a large region (e.g. Hamburg). Hence, the actual location could be out by 10 km or more but less than 100 km</td>
<td>100</td>
</tr>
<tr>
<td>4</td>
<td>Here so little is known about the exact location, and one only knows, that the location is within a state (e.g. Niedersachsen). Hence, the actual location could be out by 100 km or more but less than 1000 km</td>
<td>1000</td>
</tr>
<tr>
<td>5</td>
<td>Here so little is known about the exact location, and one only knows, that the location is within a country (e.g. Ukraine). Hence, the actual location could be out by 1000 km or more.</td>
<td>&gt; 1000</td>
</tr>
</tbody>
</table>

5.4 Location name alterations

Location names should be changed into the 26 letters used in the English language.

For names from the individual countries please follow the suggested approach:

- Germany/Austria: *Umlaute* to be replaced with the letter followed by an ‘e’, e.g.: ü = ue.
- France/Belgium: Omit accent de gues and accent de graphs, e.g.: ô = o.
- Sweden: Please change the last three letters of the Swedish alphabet and replace e.g.: ä = a.
- Poland: Please change any letter, that cannot be found in the English alphabet, knowing that for some letters, that one can only use a single letter instead of the three different letters used in the Polish alphabet, e.g.: z = z.
5.5 Country name abbreviations

For convenience we provide a short list of names and two-digit codes (see Table 5.5) for the probably most important countries associated with the European Transmission Grid.
