

Total column water vapor from GOME-2 UV-VIS and NIR measurements toward a climate data record

Luca Lelli
Christian Borger
Temenuzhka Avramova
Diego G. Loyola

Motivation: platforms

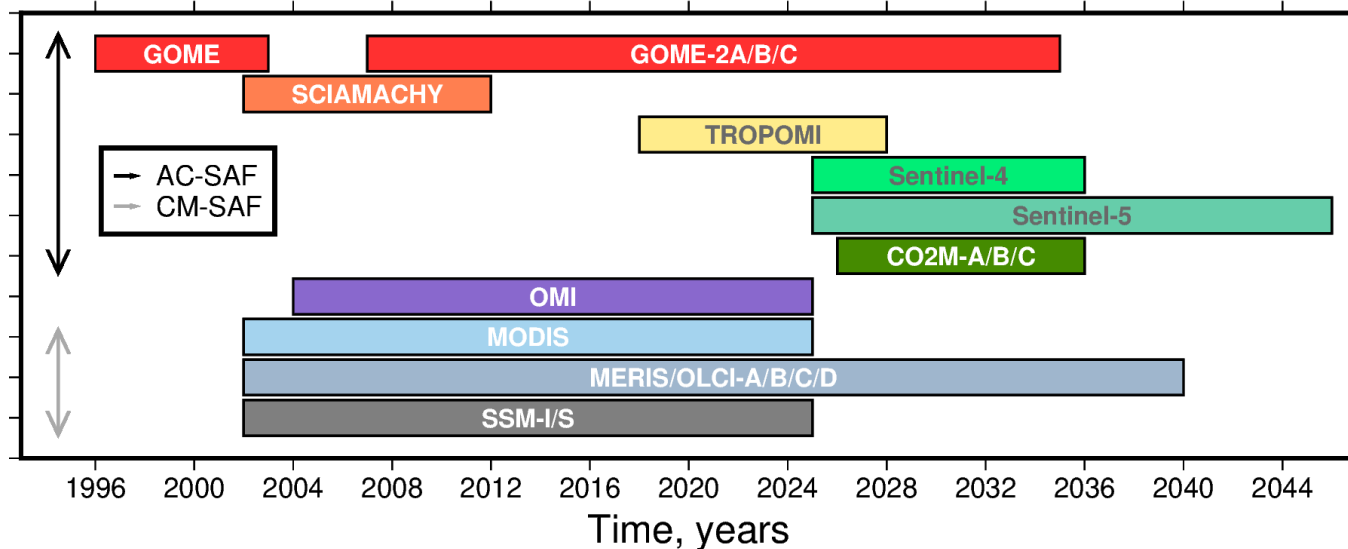

Spectral coverage

The **blue band of water vapor** is the weakest but it is sensed by more sensors and the surface is less reflective in the UV

→ best trade off between sensitivity and coverage over both land and oceans

Temporal coverage

Fitting windows are different from other works

TROPOMI (S5P) 435 – 455 nm
 GOME-2 (MetOp) 427.7 – 455 nm

GOME, SCIAMACHY, UVN (S4 and S5) yet to be defined

Algorithm: DOAS

Nitrogen dioxide

Raman scattering

Liquid water

Tetraoxygen

Ozone

Water vapor

The blue band of water vapor is the weakest but it is sensed by more sensors and the surface is less reflective in the UV

→ best trade off between sensitivity and coverage over both land and oceans

Fitting windows are different from other works

TROPOMI (S5P) 435 – 455 nm

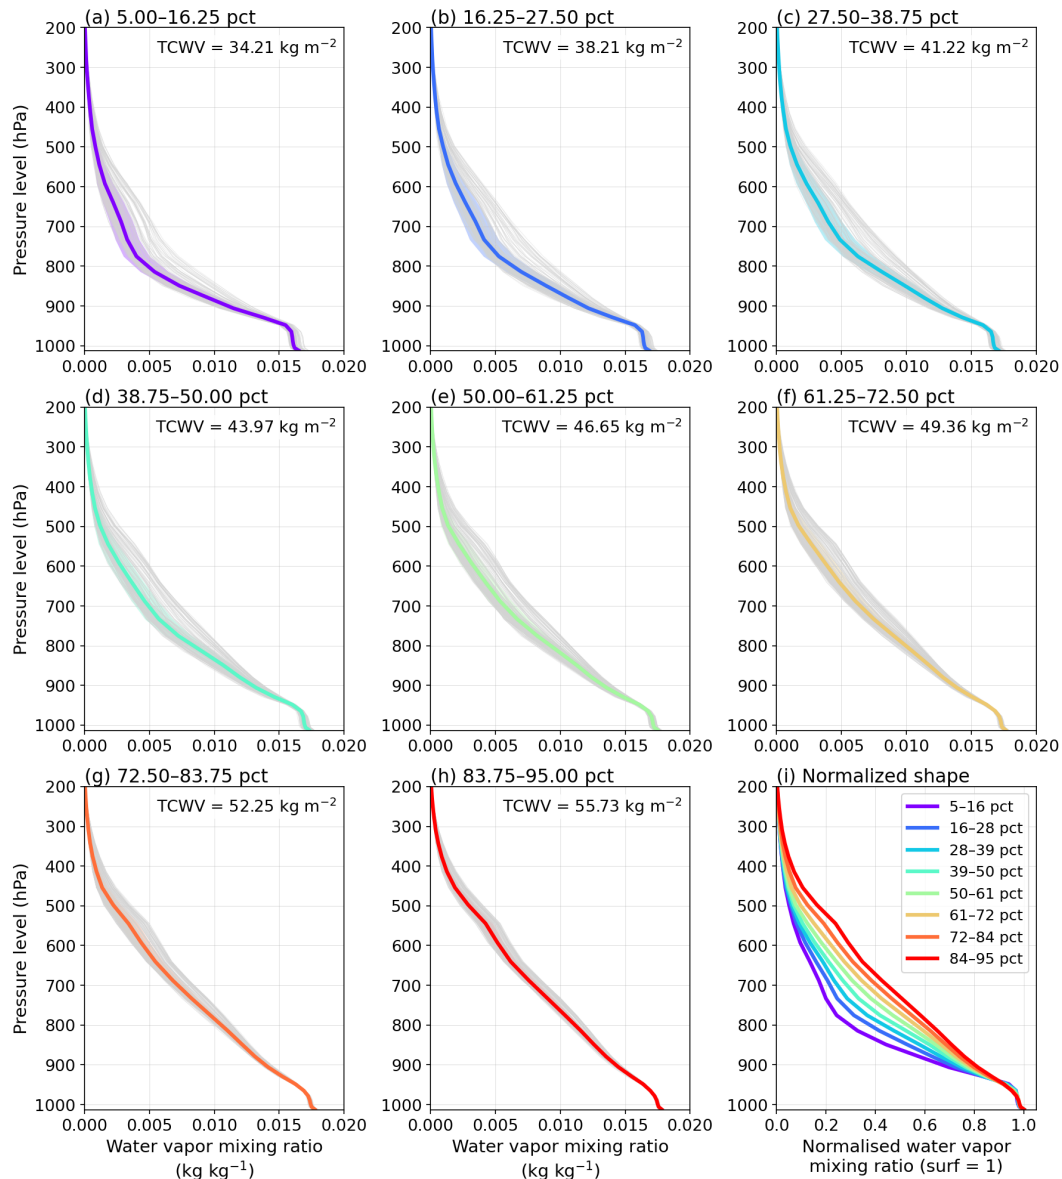

GOME-2 (MetOp) 427.7 – 455 nm

GOME, SCIAMACHY, UVN (S4 and S5) yet to be defined

Suboptimal cross-sections account for most of the residuals

Algorithm: a-priori WV profiles

Water vapor profiles – Pacific Ocean (5°S–5°N, 180°W–170°W), July
ECMWF ERA5 climatology 1979–2025, TROPOMI overpass

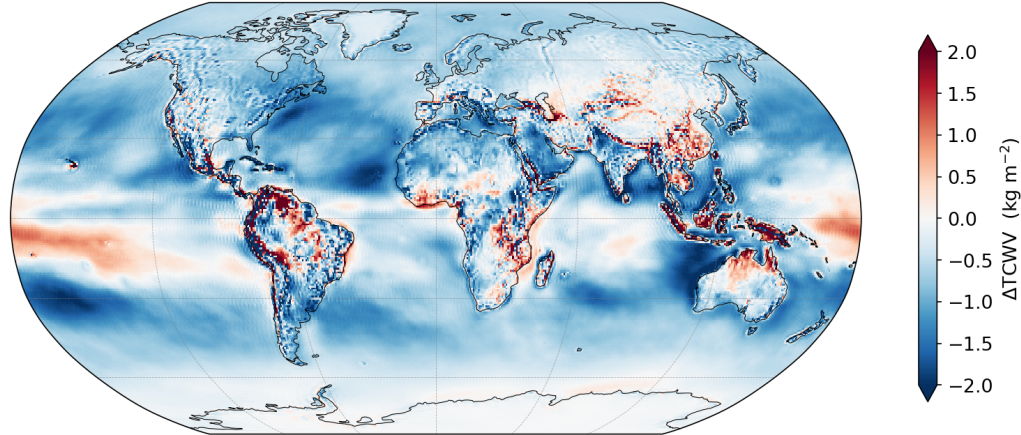

- **Prior profiles of water vapor are from reanalysis, not models**
- **Distinct profiles for TCWV range classes**
- **ERA-5 from 1979 to 2025**
- **Reads 6-hourly ERA-5 files, interpolate to satellite local overpass time, downsample to 60 levels, compute TCWV distribution → Look-up table at 0.75° resolution**
- **Iteratively compute VCD with box air mass factors to match the proper TCWV range for a given profile**

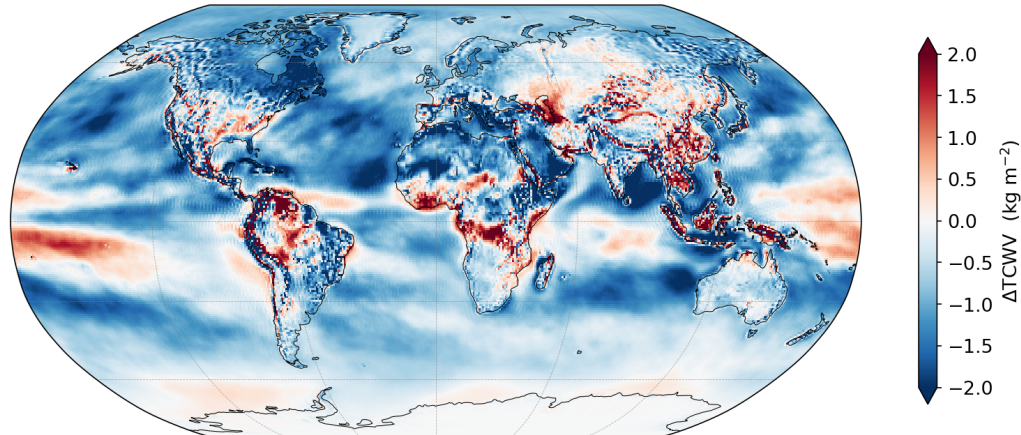

Algorithm: a-priori WV profiles

Diurnal sampling bias in TCWV:
actual TROPOMI overpass time vs fixed equatorial overpass (13:30 LST)

TROPOMI overpass – fixed-time climatology [Annual mean] global mean: -0.57 kg m^{-2}

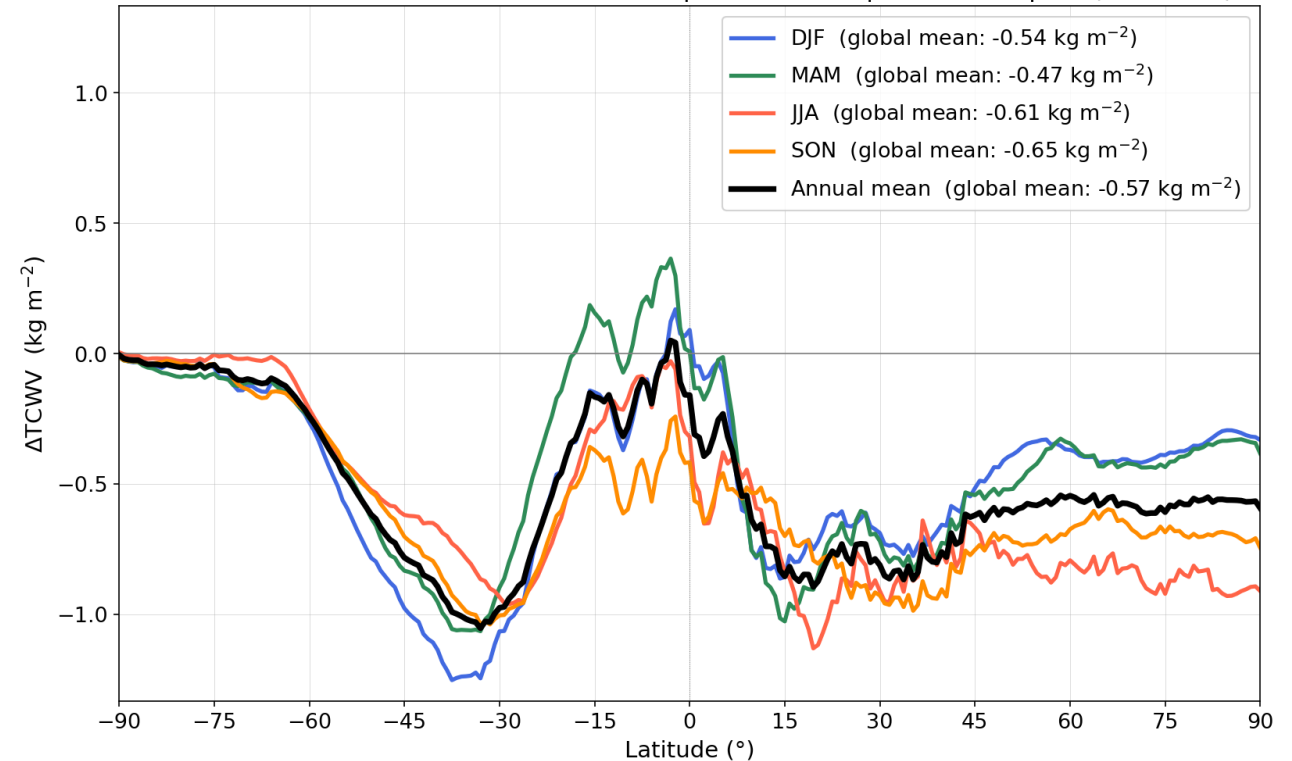

TROPOMI overpass – fixed-time climatology [JJA] global mean: -0.61 kg m^{-2}

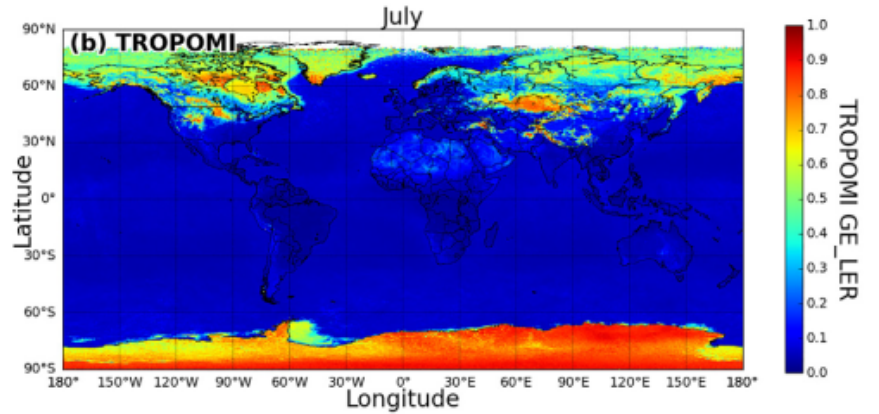

Diurnal sampling bias introduced by assuming a fixed equatorial overpass time (13:30 LST everywhere) vs. using the latitude-dependent actual TROPOMI overpass time

Zonal mean TCWV deviation: TROPOMI overpass – fixed equatorial overpass (13:30 LST)

Surface reflectivity

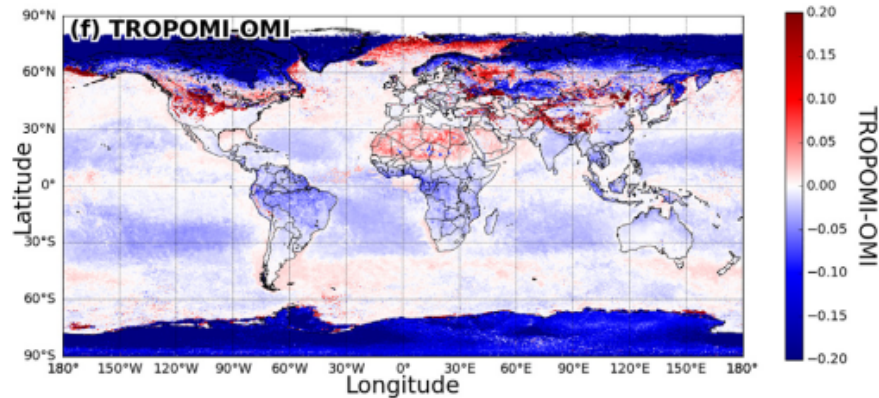

- TROPOMI surface reflectivity is

- 1) Geometric Equivalent LER = directional
- 2) co-fitted with the gas species
- 3) spectral band 435–455 nm

- OMI surface reflectivity is

- 1) Lambertian
- 2) minimum dark sky
- 3) wavelength 442 nm

GOME-2 A/B NIR intercomparison

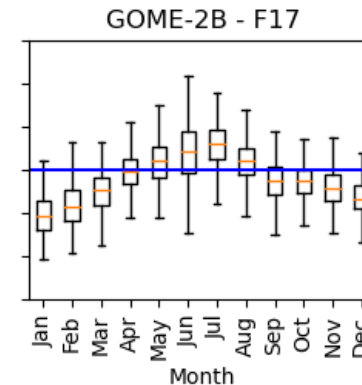

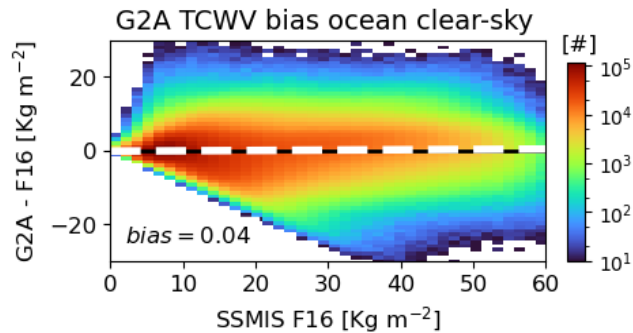

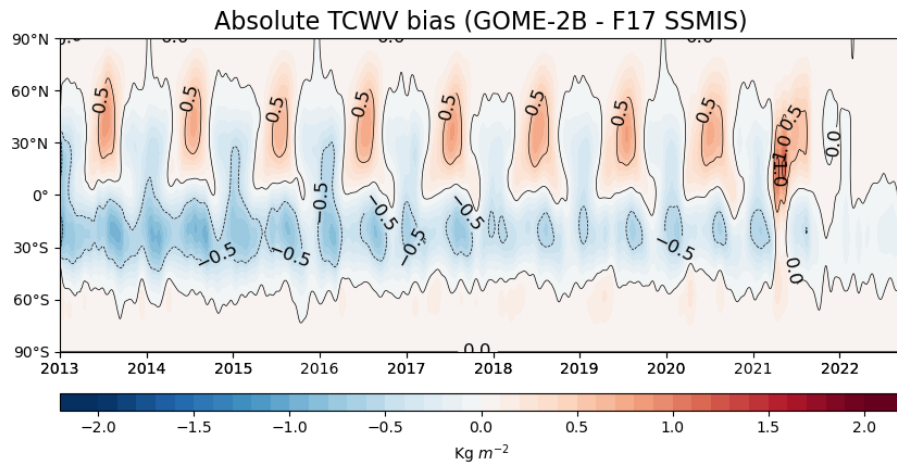

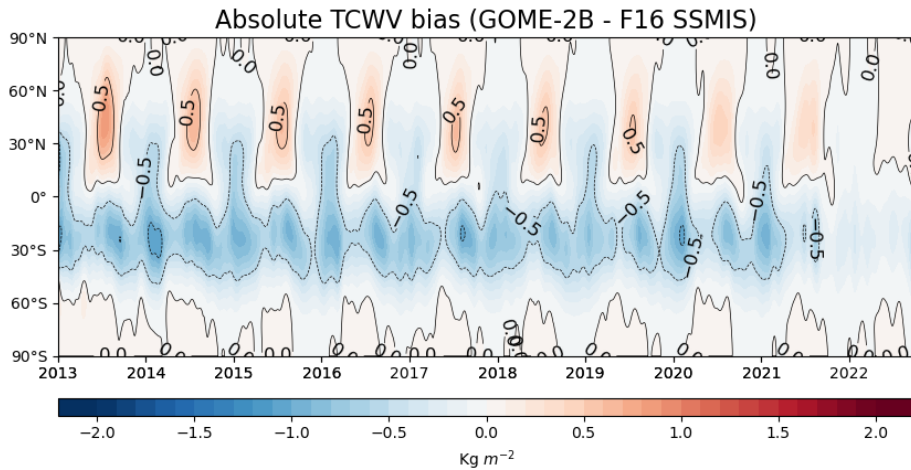

GOME-2A slightly underestimates GOME-2B ($-0.035 \pm 2.71 \text{ kg m}^{-2}$), largely due to difference over oceans.

As expected, the intra-sensor differences do not show any systematic effect and are mostly of random nature

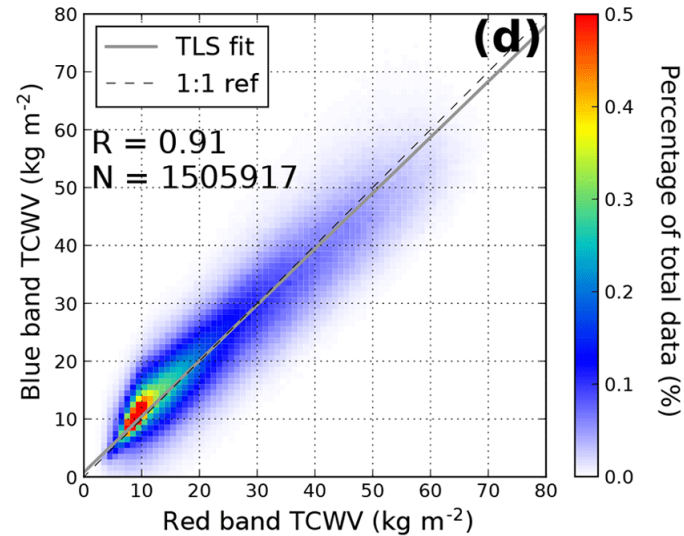

GOME-2 A/B NIR vs SSMIS F16 and F17 – ocean only

- Global long-term mean biases of less than 1 kg m^{-2}
- SSMIS microwave sensors are sensitive to in-cloud water vapor and fly also in the afternoon orbit (local time), thereby sampling a moister atmosphere
- A larger systematic bias between GOME-2 and SSMIS should be expected.

GOME-2 A/B NIR vs UV band

The mean bias between the blue and red band
January 0.12 kg m^{-2}
July -0.08 kg m^{-2}

GOME-2 UV-NIR vs other datasets

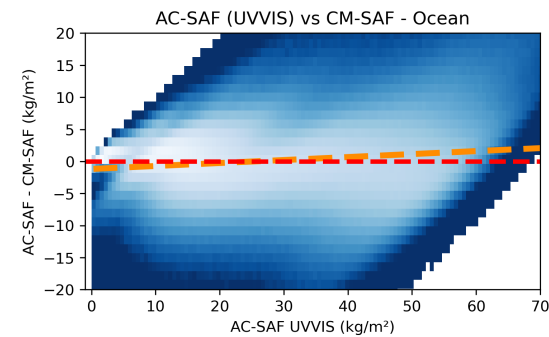

AC-SAF vs CM-SAF vs ERA TCWV 2008-2017

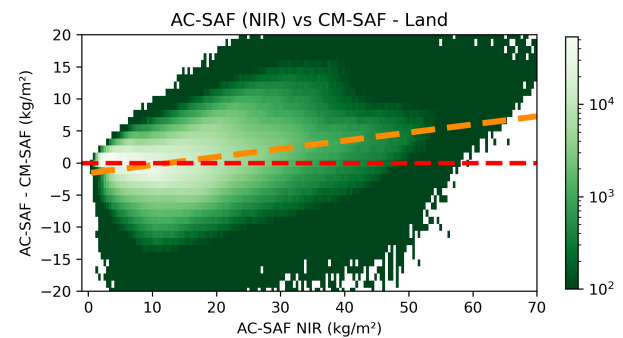

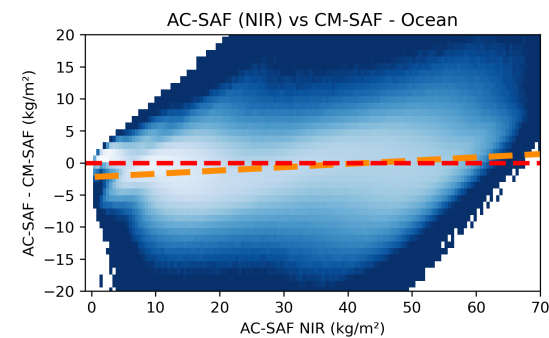

TCWV anomaly 2008-2017

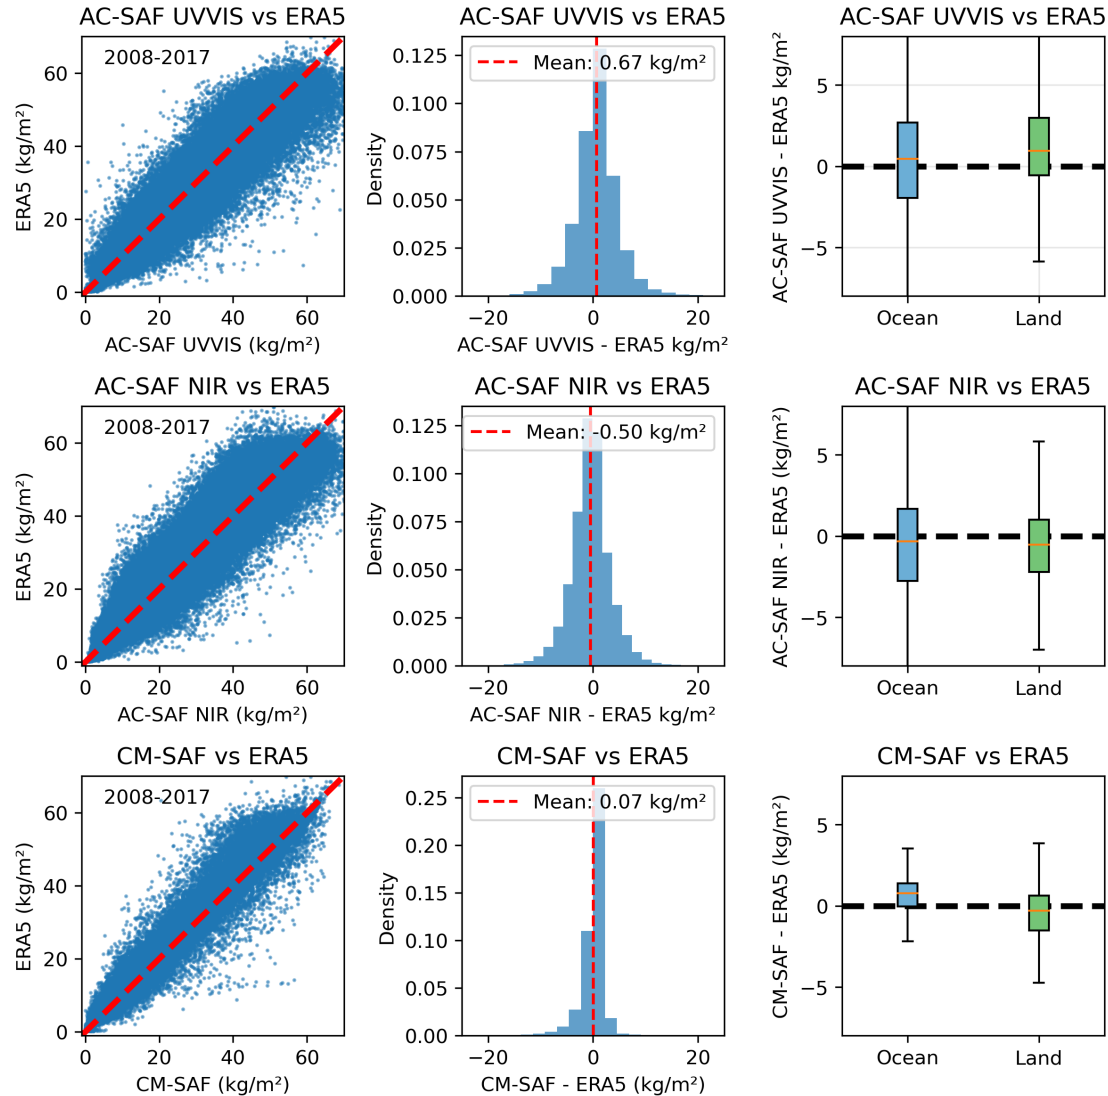

AC-SAF vs CM-SAF TCWV bias 2008-2017

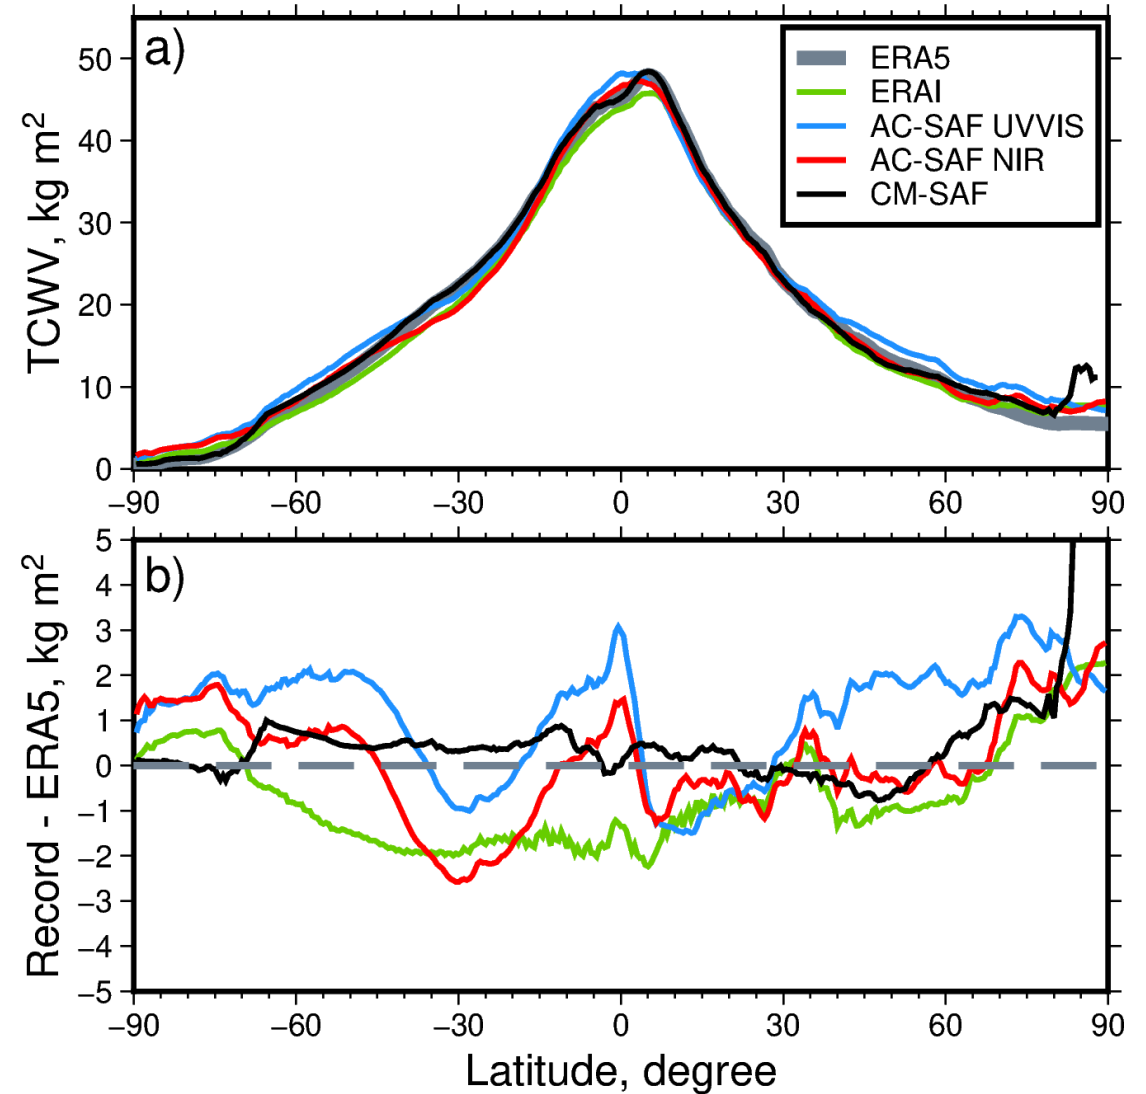

Satellite records vs ERA5 TCWV bias 2008-2017

GOME-2 UV-NIR vs other datasets

Zonal TCWV 2008-2017

GOME-2 UV-NIR vs other datasets

Satellite records TCWV 2015

a) AC-SAF UVVIS - NIR

b) AC-SAF UVVIS - CMSAF

c) AC-SAF NIR - CMSAF

d) AC-SAF UVVIS - ERA5

e) AC-SAF NIR - ERA5

f) CMSAF - ERA5

Dataset (2008-2017)	Mean±stdv	Median
AC-SAF UVVIS	19.27±12.81	16.27
AC-SAF NIR	18.02±13.11	14.39
CM-SAF	22.10±15.46	17.99
ERA5	18.48±15.68	14.01

GOME-2 full time series (NIR)

GOME-2 TCWV — All sensors: daily global mean and coverage

Deseasonalised TCWV anomalies — all sensors

GOME-2 full time series (drift)

Inter-sensor drift: GOME-2B – GOME-2A

(a) Daily bias time series and running mean (90 days)

(b) Seasonal structure of the bias (box=IQR, whiskers=10-90th pct)

Conclusions and outlook

- All satellite records show **inevitable discontinuities** because of differences in the design of the respective platforms and the continuous reprocessing and recalibration of measurements. To obtain CDRs, ad hoc corrections must therefore be developed and applied
- All satellite records show a **general spatial, zonal, and temporal consistency** in the distribution of water vapor in the atmosphere, both among themselves and with reanalysis
- Globally and long-term, the **highest TCWV value** is reported by CM-SAF (22.10 kg m⁻²), followed by ERAI (19.97), GOME-2 UVVIS (19.27), ERA5 (18.48), and GOME-2 NIR (18.02)
- **Spectrally**, the GOME-2 satellite record derived from the UVVIS band shows underestimation in a drier atmosphere and an overestimation in a moister atmosphere
- The **GOME-2 records have the lowest variance and narrowest TCWV distribution**, with this probably being the consequence of a coarser pixel size at the ground (e.g. spatial averaging)
- Spectrally and as expected, the **GOME-2 NIR satellite record is more similar to CM-SAF** than to UVVIS
- **Reprocessing and harmonization** of settings across platforms. Using L1b Fundamental Data Record (ESA-DLR project: FDR4ATMOS) → 430 - 460 nm original purpose NO₂ → no orbital drifts, radiometric-corrected, fit for climate normals → reprocessing of full record H₂O observations from 1995 (GOME) onward
