

### **Global Climate Change and Aviation - The Challenge**

David Lee, Centre for Air Transport and the Environment at Manchester Metropolitan University

Ulrike Lohmann, Institute for Atmospheric and Climate Science at ETH Zurich and Ulrich Schumann, DLR Institute of Atmospheric Physics Oberpfaffenhofen

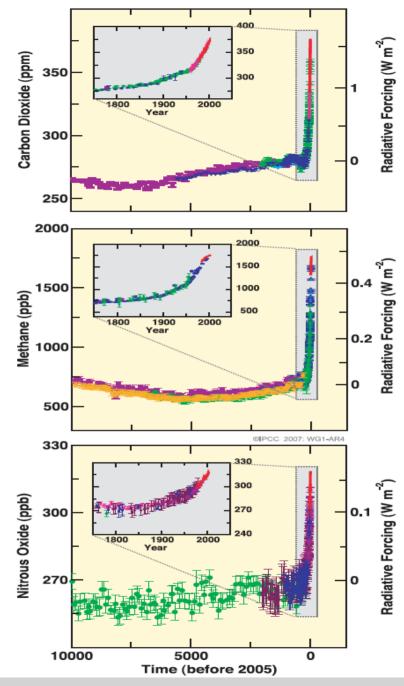

### Global warming is a reality

- Strongest CO<sub>2</sub> concentrations increase since 650,000 years
- 0.75°C warmer globally than a century ago
- Human induced radiative forcing of about 1.6 W/m<sup>2</sup>
- Most of the global warming of the past half-century is due to increases in greenhouse gases
- The future climate depends on human choices about emissions

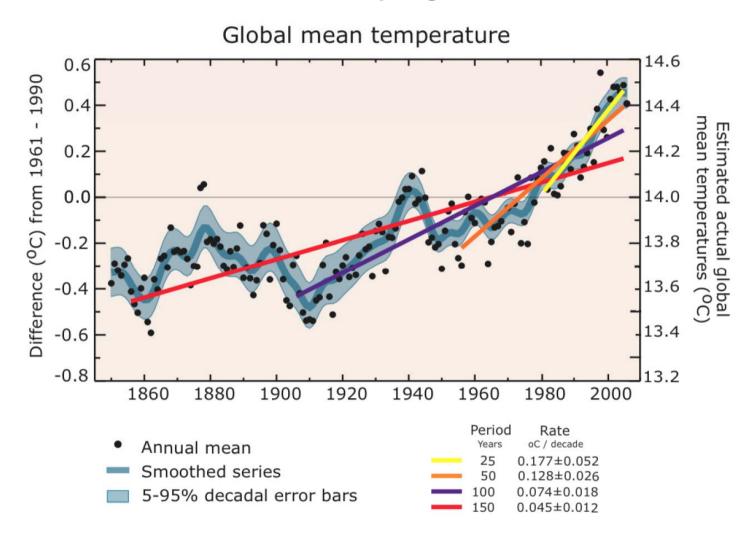

# CO<sub>2</sub> concentrations increase: unprecedented in the last 10,000 (actually 650,000) years

- Increased Growth rates of Greenhouse gas concentrations (Carbon Dioxide, Methane, Nitrous Oxide) during the last 50 years
- Carbon Dioxide (CO<sub>2</sub>) increases caused mainly by burning fossil fuels

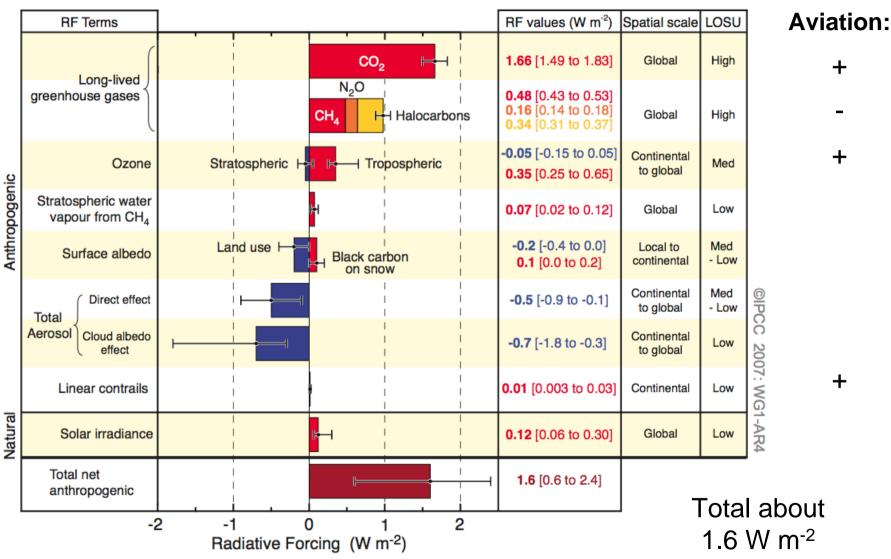

# Global mean surface temperature: 0.75°C warmer than it was a century ago

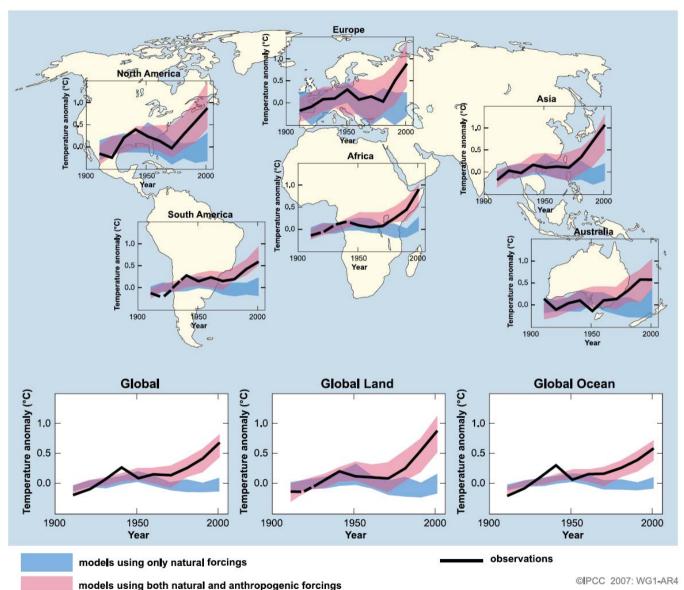

(IPCC, Fig. 3.2)

### Large Human Contributions to Radiative Forcing

# Very likely (>90%) that most of the global warming of the past half-century is due to increases in greenhouse gases

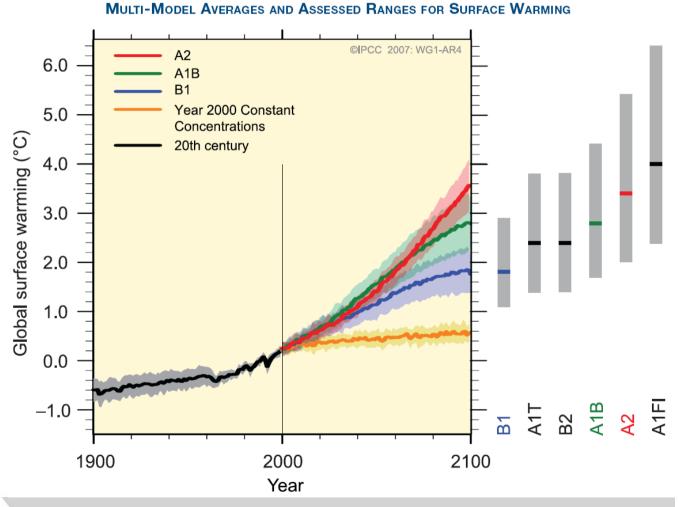

## The future climate depends on human choices about emissions

Growth to 600 – 1550 ppmv CO<sub>2</sub> equiv (B1 – A1FI)

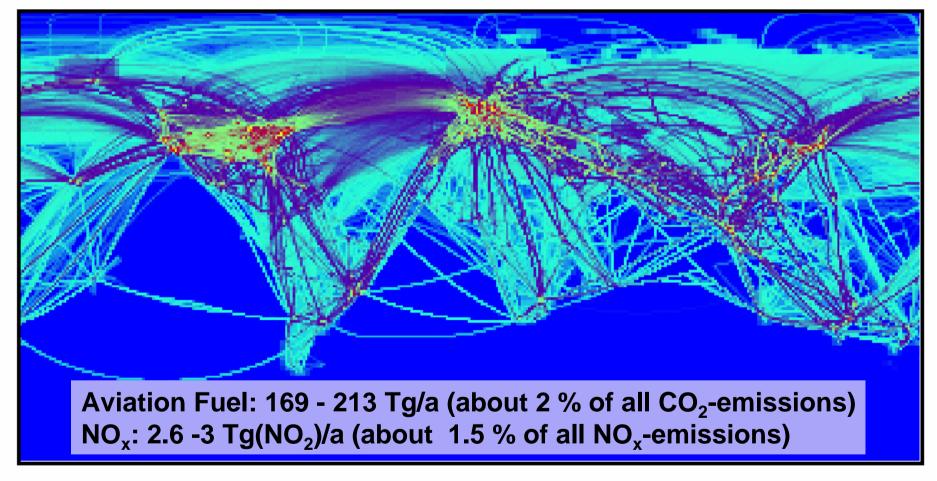

corresponds to +1.8°C to +4°C [likely 2.4-6.4°C] by 2100

### Climate Impact of Aviation

- Global aviation contributes to climate change by emissions of carbon dioxide (CO<sub>2</sub>), nitrogen oxides (NO<sub>x</sub>), water vapour, particles, contrails and cirrus changes.
- Carbon dioxide is the most important greenhouse gas. Its effect is independent of the altitude at which the emission occurs.
- Nitrogen oxides from aviation at subsonic cruise altitudes enhance ozone formation and reduce methane; both are greenhouse gases.
- Water vapour and particles (soot etc.) emitted at altitudes near the tropopause can induce contrails and cirrus clouds, likely enhancing the greenhouse effect.

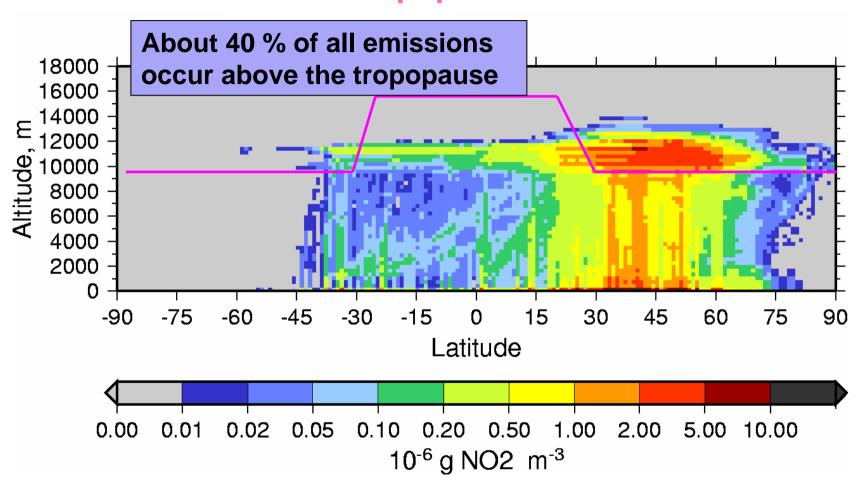

longitude (degrees\_east)

(AERO2K, 2005)

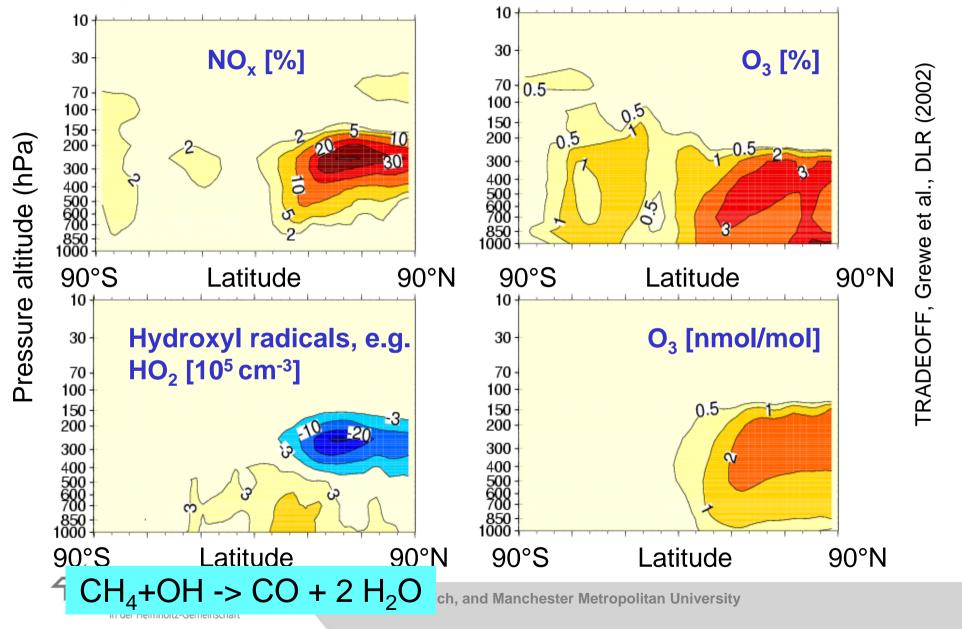

# Vertical Distribution of Aircraft Emissions and Tropopause

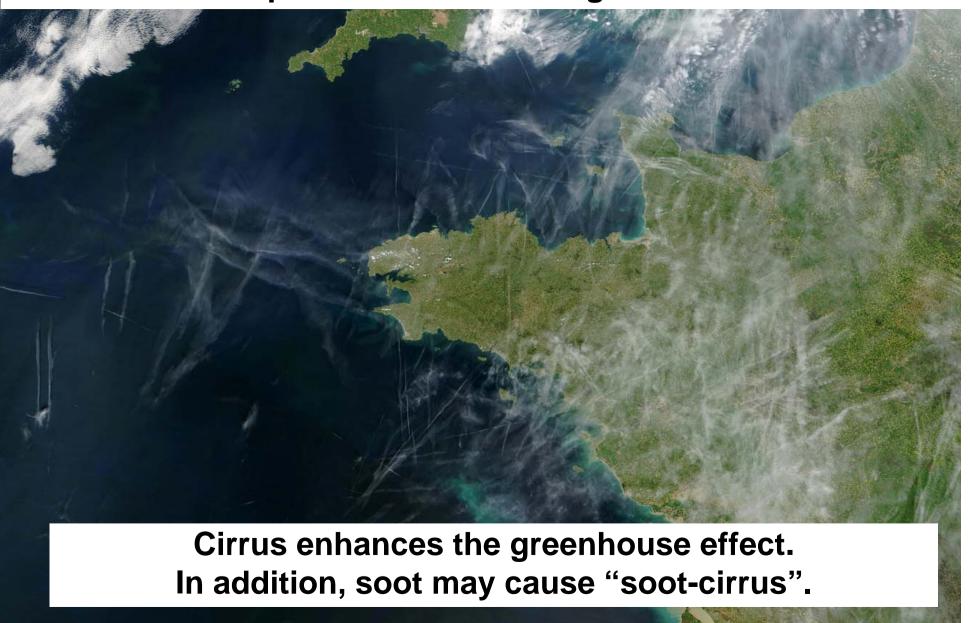

(AERO2K, 2005)

# Aviation increases Nitrogen Oxides (NOx), Ozone (O<sub>3</sub>) and Hydroxyl Radicals (OH) concentrations in Upper Troposphere

# Contrails from cruising aircraft and soot cause cloud changes: we see line-shaped contrails evolving into "contrail-cirrus"

# Contrails and soot from cruising aircraft cause cloud changes which mostly contribute to warming

Contrails are caused by water vapor emissions from aircraft flying in cold and humid air masses

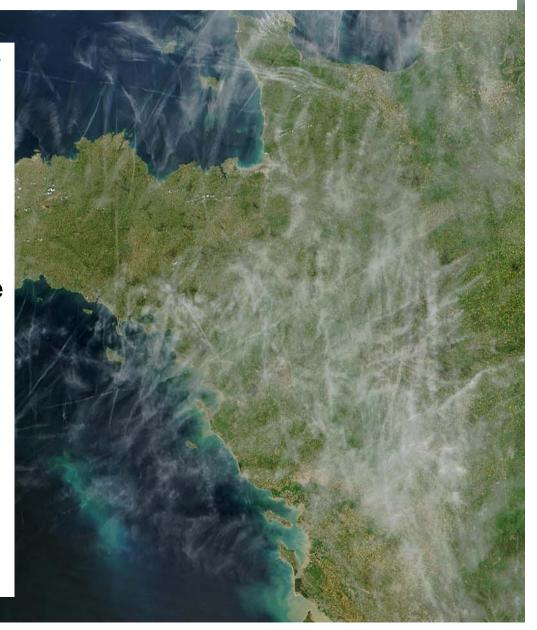

Soot and other particles change contrails and cirrus properties

Line-shaped contrails are detectable from space

The total cirrus change is estimated with still large uncertainty

Cirrus and contrails heat during night

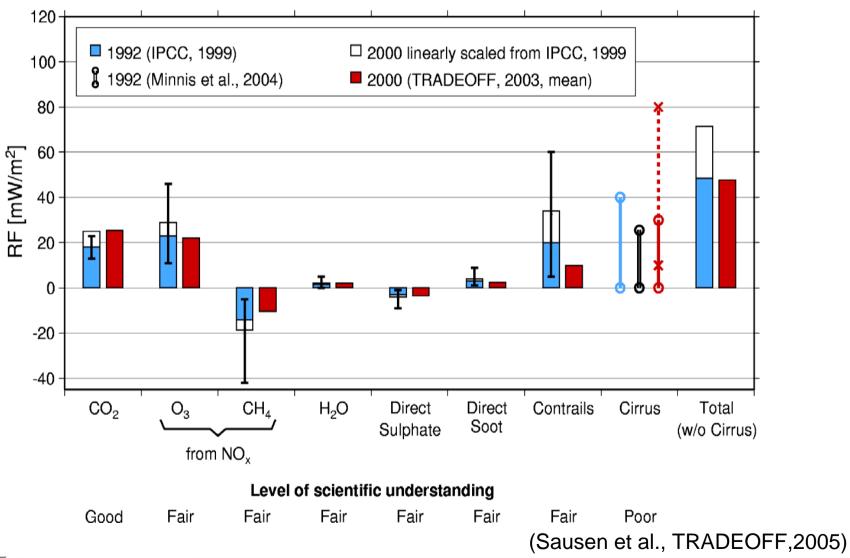

They heat or cool during day

# Radiative Forcing and Temperature Change induced by Aviation

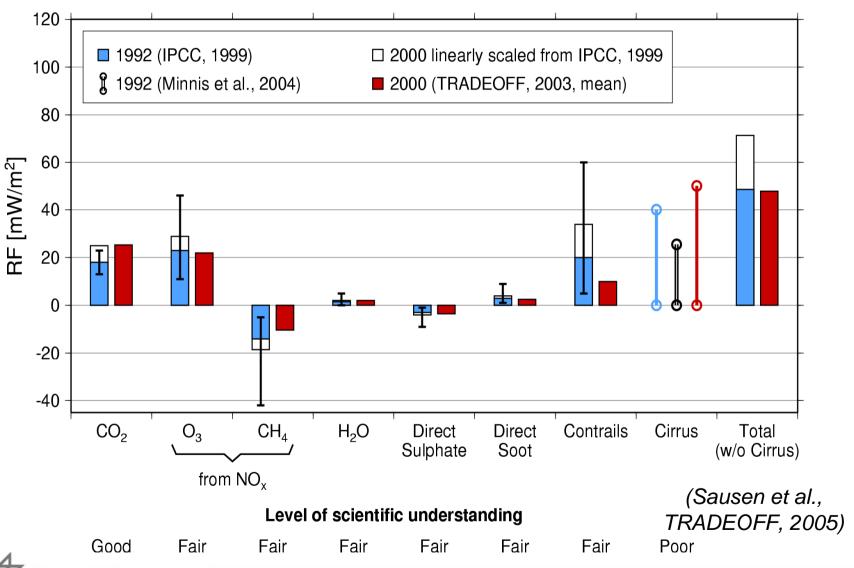

- Global aviation contributed to Radiative Forcing so far about 0.05 W/m<sup>2</sup>.
- These are about 3 % of the total (about 1.6 W/m<sup>2</sup>) radiative forcing from all anthropogenic effects
- The largest uncertainty comes from aviation contributions to changes in cirrus clouds, which are not included in the total therefore.
- Including the presently know uncertainties, the aviation contribution is estimated within the range 2 to 8 %.
- Global aviation contributed to the observed global warming of 0.7°C about 0.02-0.03°C (ca. 3-4 %), so far.

### Radiative Forcing until 2000 from Global Aviation

### Radiative Forcing until 2000 from Global Aviation

#### **Trends**

Aviation fuel consumption (CO<sub>2</sub> emissions) grew globally by 2-3 % per year from 1990 – 2004.

**Aviation NOx emissions grew faster** 

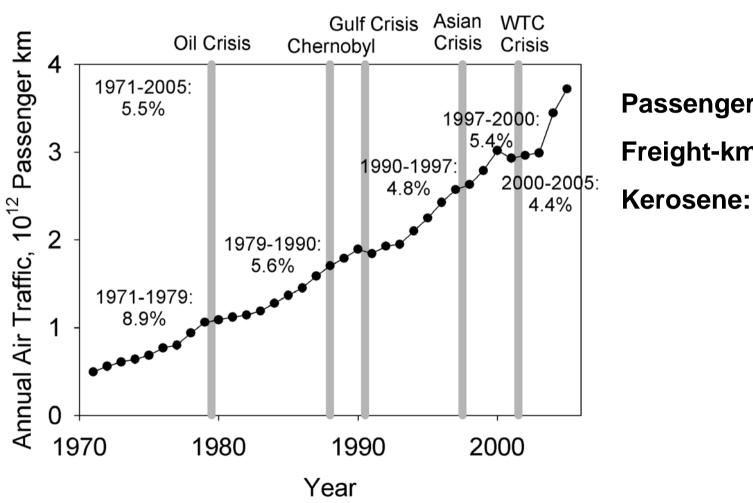

Further growth of global fuel consumption and global emissions of CO<sub>2</sub> and NOx is to be expected.

Scenarios of civil aviation CO<sub>2</sub> emissions in 2050 show a potential increase by factors 3.3 - 5

If aviation emissions continue to grow while other emissions get reduced, the relative importance of aviation contributions grows

### **Trends**

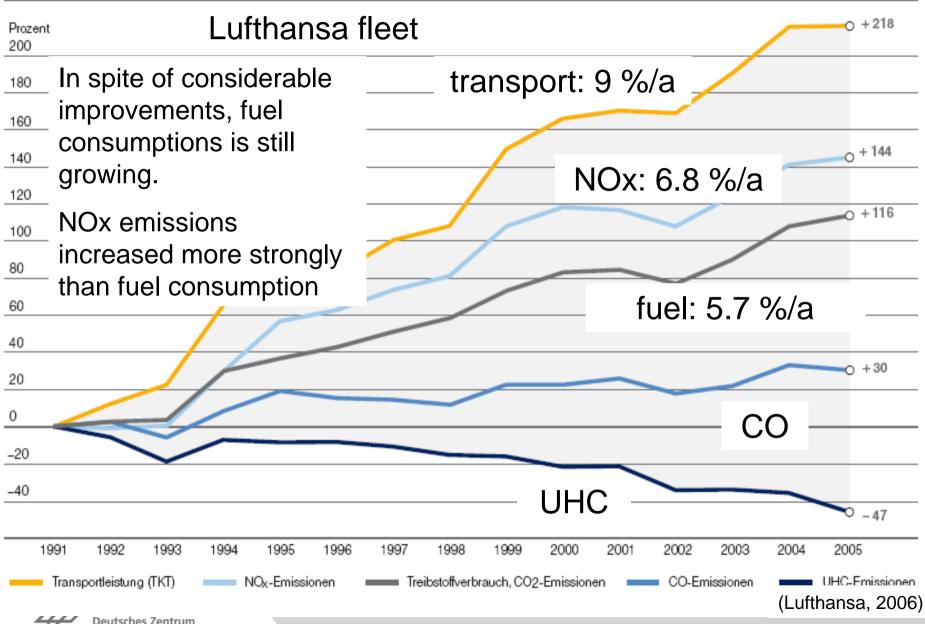

1991-2004:

Passenger-km: 4.6 %/a

Freight-km: 6.4 %/a

Kerosene: 2.1 %/a

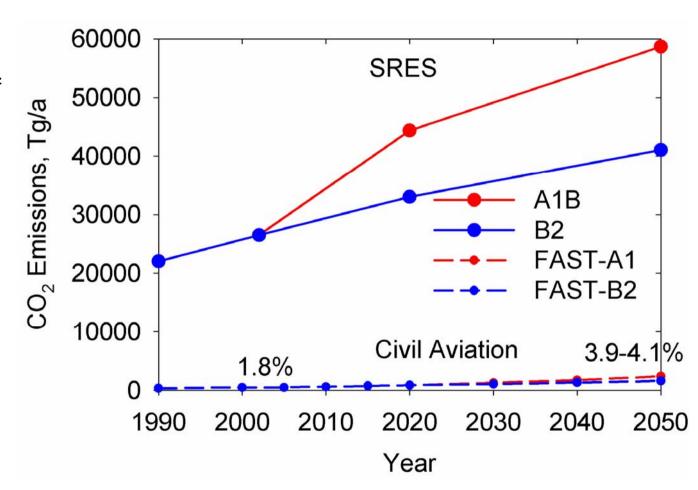

(Schumann, 2007)

### Future Emission Scenarios for CO<sub>2</sub> from all sources

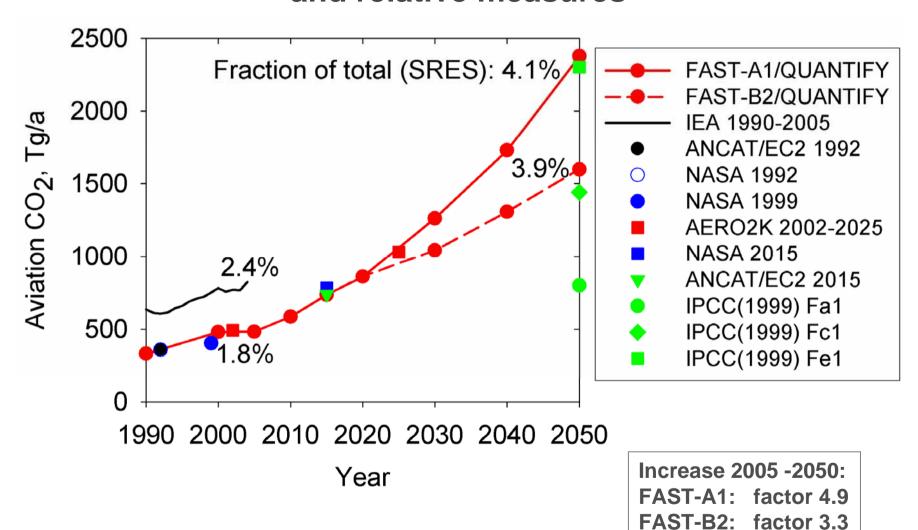

A1B: rapid economic growth, balance across all sources, fast intro. of new technologies, strong globalisation

B2: moderate
economic growth,
diverse technological
change, more
oriented towards
environmental
protection, focus on
regional levels

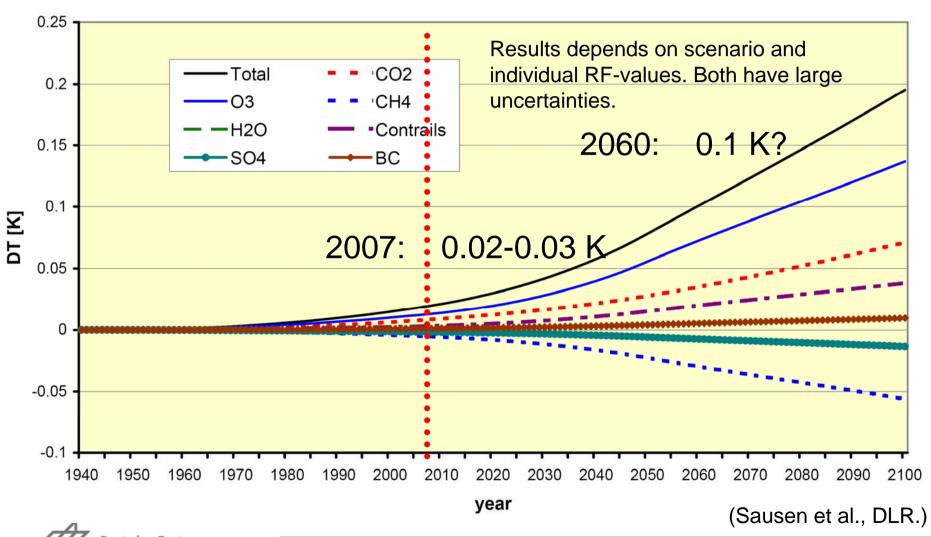

### Scenarios: Aviation CO<sub>2</sub> increases in absolute and relative measures

# Global aviation contributed to the observed global warming of 0.7°C about 0.02-0.03°C (~3-4 %), so far

### **Conclusions**

Global warming is observed and largely caused by human drivers

Climate protection requires reductions of the total greenhouse gas emissions, including those from aviation

The aviation share in CO<sub>2</sub> emissions is presently about 2 %

Hence, increased fuel efficiency is important (for several reasons)

In addition, cruising aircraft impact climate by NOx and contrails

The aviation share in radiative forcing is presently 3 % (range 2-8%)

Scenarios of aviation CO<sub>2</sub> emissions show potential increase by factors 3.3 – 5 until 2050

NOx and Contrails offer special chances for climate mitigation

Largest uncertainty and possibly largest contribution from contrail cirrus

The contrail issue needs higher attention by ACARE and others
